In these ways, and in other indirect ways, it will be seen that to keep a tuberculous herd is indeed a bad policy and not a paying proposition. If only every farmer grasped this fact there would soon be a great alteration in the respect. He must realize that tuberculosis is a very contagious disease, that one badly infected animal can infect a whole herd, and that very few cows appear to have any immunity against it, or live long enough to recover from it.

The producer will ask: If I get rid of my tuberculous cows, alter my cow-byres, put up a sterilizing plant and produce pure milk, will the public appreciate it or give me more money for it? Until quite recently the answer would be No, because the public is very ignorant on the subject, and further, there is always a tendency to buy in the cheapest market whatever the quality of the milk, and wherever it is produced. I am happy in being able to say that a system has been inaugurated for producing milk of the highest quality, and the public, realizing its value is beginning to demand it and is willing to pay a small additional sum for it. I refer to the graded milks which are recognized by the Ministry of Health.

In October 1918, when first issued Grade A and Grade B licences, and up to March 1920, only 6 farmers were selling Grade A, 30 were selling Grade B (14 of these farms being in Scotland), whilst 13 retailers were licensed for the distribution of these milks. At the end of 1921 there were 41 Grade A (certified) and 22 Grade A licences, but there was a remarkable increase in the distributors to 181. In December, 1924 there were 74 farms producing certified milk, 66 producing Grade A tuberculin tested milk, and a large number of Grade A herds, while the distributors had increased enormously.

I am proud to say that most of this Grade A tuberculin tested milk is produced in and around Reading and some of this milk is being retailed at the same price as ordinary milk, while in other cases only a penny a quart extra is being charged. When sold wholesale the producer gets 3d a gallon more, and I hope some of these producers will be here to say that they can pay expenses with perhaps a small margin of profit at this price.

It has been estimated that the producer will obtain on an average from £8 to £10 a year extra from each cow for this milk, and in an average herd of 50 cows this will mean £400 to £500, which will pay for any number of tests and should compensate him for the decreased value of his reactors, especially as there will be no loss from "wasters."

Certified milk has to be produced under the best possible conditions, is bottled on the farm, entailing considerable expense and obtains a better price so the sale of this class of milk must necessarily be limited, but there is no reason why Grade A tuberculin tested milk should not be used by all, and it has been found to be cheaper to pay this small additional amount, as there is less souring, less waste, and the milk is more appetizing and nutritious. There is really very little difference between this and certified milk, except that it is bottled by the dairyman instead of on the farm and the bacterial count allowed per cubic centimetre is 200,000 instead of 50,000. These two milks must not be put mixed. Ordinary Grade A milk, on the other hand, differs from the two former grades in that the cows are not tested with tuberculin, so there are not the same safeguards against tubercle bacilli being present in the milk, but it may be pasteurized if a special licence be obtained.

One great advantage with all these milks is that the cows are periodically inspected by a veterinary surgeon for the purpose of discovering any diseased conditions that may injuriously affect the milk. A certificate is given showing particulars of any cows with any of the following abnor-

militia and these must immediately be excluded from the herd, either temporarily or permanently. These conditions are tuberculosis of the udder, tuberculosis with emaciation, chronic cough with definite clinical symptoms of tuberculosis, anthrax, foot-and-mouth disease, mastitis, abscess of the udder or retained placenta. This provision is a great safeguard to the public and also to the owners, as it is not uncommon to find men continuing to milk cows with mastitis without they or the owners realizing the fact. No doubt many childish ailments, such as diarrhoea, skin eruptions, and febrile conditions, are due to imbibing milk containing coliform bacilli or various pus-forming organisms.

It, as I have endeavoured to show, clean milk can be produced on most farms at a small profit, and it is to the advantage of the consumer to buy it even at a small extra cost than why cannot it be obtained everywhere? The answer is that the producer is waiting for a market and the distributor for an assured supply, thus a vicious circle is produced. If only there was a general demand for this milk it would soon be produced. In Reading production preceded demand, which had to be created. If only medical men throughout the country would advise it which they can wholeheartedly do, for children, invalids, schools, hospitals, and other institutions, not forgetting the general public, there would soon be such a demand for clean milk that the whole of the milk supply of this country would be revolutionized.

If the discussion on this subject has done no more than convert some members of the British Medical Association and of my own profession to be the pioneers of clean milk in their own districts, it will not have been in vain.

III—MR J H MAGGS, Chairman of United Dairies Ltd

THE POINT OF VIEW OF THE DISTRIBUTOR

THE production side of pure milk will have been dealt with by the previous speakers, and I am deputed to open the discussion on the distribution side.

At the time of preparing this paper I am, of course, not in a position to know the views of those eminent authorities who will have preceded me, and who will have defined what standards should, in their opinions, be applied to pure milk. As a layman who has to carry on the distribution of milk obtained from thousands of farms, I am content to accept the standards adopted by the Ministry of Health in its Designations Order as reasonable from the standpoint of bacterial content. These designations apply to Certified, Grade A (T.T.), Grade A, Grade A Pasteurized, and Pasteurized.

Now the volume of tuberculin tested milk produced is, so far as I am able to judge, not likely within this generation to be more than a small percentage of the supply required for our population. If the figure usually accepted of the proportion of retching (tuberculous) cows in English herds is correct—and I have no reason to disbelieve it—it must be obvious that any immediate order to destroy such cows would create a famine in milk which would be far worse for the health of the community than the possibly slight risk of tubercle infection in drinking such milk. Should, however, the work which is being done by Spaulinger and others on the lines of immunizing cattle by serum treatment prove successful, the whole aspect of the case would be altered. The Tuberculosis Order, the reintroduction of which is now suggested would, in my opinion, be sheer waste of public money without any compensatory benefit, unless accompanied by rigorous inspection, which is not, I believe contemplated. Indeed in so far as it would satisfy public opinion it would be even dangerous.

Of milk-borne diseases however although tuberculosis is most in the limelight it is, I gather the prevailing medical opinion that the possible conveyance of scarlet fever, diphtheria, sore throat, typhoid and infantile diarrhoea, is more to be feared, and requires to be guarded against as far as possible. Of course, none of these is attributable to the cow herself, but milk-forming as it does such

an ideal medium for the growth of bacteria, is peculiarly liable to infection from other than bovine sources and I would emphasize particularly from domestic sources.

As regards tubercle, I would remind you of the statement made in the Registrar-General's annual report for 1921 as follows: "The fall in infant mortality attributed to tubercle is so rapid and continuous that the disease is ceasing to be an important contributor to the death rate." I am sure that dried milk vendors and others have claimed the credit for the improved mortality figures and I have pointed out that since my company commenced retuling milk in London the infant mortality rate has rapidly fallen. No doubt there are many factors at work but all must admit that the credit is mainly that of the scientific and medical side working through enlightened sanitary authorities and a public opinion which has been awakened and educated by the scientific side.

On the lowest grounds of self-interest, apart altogether from the standpoint of public health, the milk distributor must consider on the scientific data available to him, the best and most certain means of ensuring that his deliveries of milk are safe and palatable, and of the highest possible food value. He may obtain the best clean milk from the cow but between the cow and the household the opportunities of contamination are many. To a certain extent these are eliminated where, as in the case of certified milk, the milk is bottled at the farm although even there a risk is run—a cow may have become tuberculous since the previous testing, or a milker may be suffering from infectious disease not yet diagnosed as such. Such cases are not imaginary—they have occurred, and even certified milk has spread disease. Dr Leonard Findlay is quoted as having stated that "Recently five cases of bovine tuberculosis had occurred in infants fed entirely on Grade A milk from a most reputable dairy." Fortunately, science has placed at our disposal a simple process known as pasteurization, which, if properly performed, eliminates probably 99 per cent of the risks, without damage to the food value or the palatability. It is claimed that this process destroys all pathogenic organisms and, provided that pasteurization is immediately followed by bottling, the dairyman will have a safe milk. In the minds of some of you there may be still a prejudice against any treatment of milk whatever, but I venture to say that the more that is known about milk and about the effects of pasteurization, the more will such prejudice disappear. In most of the large cities of Canada and the United States of America, pasteurization of all but certified milk is compulsory. In Denmark even the skim milk for pig feeding must be pasteurized. In this connexion the statement of the National Commission on Milk Standards set up by the United States Government very well represents the prevailing opinion. I will quote:

The Commission think that pasteurization is necessary for all milk excepting Grade A Raw Milk [which corresponds with our certified]. The majority of the Commissioners voted in favour of the pasteurization of all milk including Grade A Raw but since the action was not unanimous the Commission recommend that the pasteurization of Grade A Raw Milk be optional.

I quote also from *A Half Century of Public Health*, published for the American Public Health Association:

The feeding of commercially pasteurized milk under the auspices of the City of New York to many thousands of infants at the Baby Health Stations constituted the most extensive infant feeding experiment the world has ever seen and demonstrated conclusively that such milk was entirely satisfactory as a safe and wholesome food for infants.

In claiming pasteurization as the distributors' sheet anchor I do not for a moment wish it to be thought that I disparage the work that has been and is being done to clean up the farms. Indeed I regard it as most important and there is in my experience very definite ground for congratulation to Dr Stenhouse Williams and his staff for the work they have accomplished in this direction. The Ministry of Agriculture, too, is keenly alive to the education of the producer of milk in clean methods. My own company does all in its power by young farmers' club, clean milk competitions, farm inspections and general educational means, to improve the supply at its source. Many

producers have been frightened by the expense which they thought would be involved, but there is abundant evidence now that the cost of cleanliness in milk production need not be appreciable, and moreover, I have no doubt in my own mind that it is to a large extent, if not entirely, counterbalanced by increased yields and the better health of the stock.

All the best elements in the distributive milk trade desire, I am sure, still closer co-operation with the medical profession and sanitary authorities. You view necessarily, and rightly, carry great weight with the consumers. From time to time great harm has been done, not only to the industry, but probably also to general health, by "scare" paragraphs in the press on the subject of milk. In your warfare against disease I am convinced that the great majority of you appreciate the value of pure milk. Some of my friends have used, as a slogan, "A pint a day keeps the doctor away"—very likely, but does not the advent of the doctor usually mean two pints a day?

You can educate the public mind to discriminate between good milk and bad, and arouse public opinion to demand a safe, clean milk supply. Legislation in this country, both national and local, does little for the betterment of the milk supply. The improvements which have come here, in the main, been initiated and carried through by enlightened members of the trade itself. The farmer or distributor who lays himself out to do his business clean has very little encouragement when he sees his neighbours going on in their old careless ways with impurity, and able to sell their milk at the same price, in the same market. Inspection of dairies and cowsheds is, in many cases, an absolute farce, and, so far as the sanitary authority is concerned, provided the liquid sold is milk containing 3 per cent of fat and 8.5 per cent solids not-fat, it will pass. In the light of present-day knowledge, that is not a healthy state of affairs.

The only method which I know that will satisfactorily discriminate between clean milk and other is the bacteriological count, and it should not be impossible to insist that all milk intended for human consumption should fall below a certain count. For a start, the standard for raw milk would have to be fairly liberal, but as time goes on it might be tightened up. Just as an indication of what is being now obtained, in the month of March, out of 60 bulk samples of raw milk taken in our various London plants, 41 were between 200,000 and 500,000, whilst 19 fell below 200,000, but all except one contained *B. coli*. After pasteurizing, the milk (the bacteriological content of which has been reduced to about 5,000) is delivered either in bottle or by can, and whilst we spare no effort to see that the cans are clean we usually find that when we examine the same milk on delivery to the householders the can delivery contains nearly ten times the bacteria of the milk in the bottles.

It would therefore appear to me that if the medical profession regards the presence of bacteria, and particularly *B. coli*, as prejudicial to health, it could quite reasonably demand that, at any rate in the larger centres of population, the milk supply should be such as to comply with the requirements of the Milk (Special Designations) Order, thus would of necessity, in my view, imply that it should be bottled.

It is probable that if the distributor adapted his methods to meet these requirements the cost would not be more than one halfpenny a quart above the admittedly unsafe methods frequently adopted at present, and if—as we might perhaps reasonably assume—the better milk led to increased demand, the cost of distribution might ultimately be still further reduced.

Assuming that the farmer and the distributor have done their parts conscientiously, that good work is often speedily nullified when the milk enters the consumer's house, it is there that the most serious contamination often occurs. Left about in hot kitchens in open vessels, it speedily becomes swarming with bacteria.

May I ask you to co-operate with us in our efforts to educate the public not only to demand clean milk, but to keep it clean and cold when they have obtained it?

GENERAL DISCUSSION

Professor WALTER HALL (Bristol University) had observed in the addresses a tendency to get away from the title of the subject. He had hoped that the discussion would turn on the ideal of how to obtain pure milk, rather than on a defence of the methods at present used. He was convinced that the methods of collection of the milk were not thorough. Clean milk could be produced at a better standard than the Government laid down. A bacterial count of 200,000 was not good even in summer—200 is possible. In his opinion the personnel at the farm was the first important matter, and the education of this personnel should be aimed at. Legal powers were best employed in an advisory capacity. Help should be offered in improving method, rather than the adoption of oppressive measures, because, in his ignorance, a farmer had not reached a particular standard.

Mr CUMBER (Reading) said that the cost of the various grades of milk had been settled by the National Farmers' Union and the Dairyman's Federation, but the milk supply was not satisfactory. What was wanted for the elimination of tuberculosis was the removal of the source of infection and the isolation of reactors to the tuberculin test. Testing an animal need not cost its price more than £1. The slaughter of reactors was not necessary; they should be isolated. Mr Cumber thought that it cost much more than 1d. a gallon to keep milk clean but 3d. more a gallon for clean milk paid. For his part he preferred his milk raw, but he knew of a London hospital which refused to be interested in the matter because all its milk was pasteurized. He doubted whether in poor homes the parents could afford the extra cost of supplying fruit juice. Milk that would keep clean could be produced; he had had milk tested after a long delivery round, and had found its bacterial count to be only 850 per cubic centimetre.

Mr R. BOUTFLOU (Agricultural Office, Wilts) advocated milk competitions as a method of education in the production of clean milk. At the last competition in Wiltshire there were thirty or forty entries, and after the competition visits were offered to those farms from which came milk with large counts. Tuberculosis was a legacy of mismanagement in the past. Better methods of feeding were producing healthier cows. Cowsheds were not a large factor in producing the disease.

Major ROBERT CURTIS (Abingdon) said that a clean product should be demanded and not merely expected. Much uncleanness was due to lack of supervision. There should be supervision of all products, and the duty should be penalized. The only protection offered to the consumer at present was pasteurization by benevolent distributors. And the bulk of the "serums," when the milk producer had finished with them, went to the butcher.

Mr J. T. QUINTON (Liverpool) thought the Tuberculosis Order was of immense advantage. It made possible a quick search into the source of trouble. In the visitation of farms there had been a great change. Farmers were now ready to receive and listen to advice, and accepted suggestions for improvement. Legislation had made many farmers come to the milk more quickly than anything else could have done. Mr Quinton wanted a better standard than 3 per cent for fats and 8.5 per cent for solids not-fat.

Mr J. C. COLEMAN (Swindon) asked whether Mr Buelley meant that tuberculosis was the most dangerous of the most prominent disease. Very few reacting cows gave tuberculous milk. The tuberculin test was very reliable, and in 164 cases of slaughtered reactors tuberculous lesions were found in every one. The intradermal reaction was said to be fool-proof.

Dr H. SCURFIELD (Folkestone) asked Mr Myle how frequently tuberculosis was reintroduced in tubercle-free herds and how the reintroduction was explained.

Dr STENHOUSE WILLIAMS stated that the papers presented that afternoon were all based upon the assumption that the New York method of supplying milk was the

ideal to be aimed at. In effect that method provided a supply of milk of which 2 per cent came from tuberculin tested cows, and was sold at a price which was beyond the pocket of the average consumer: the remaining 98 per cent was pasteurized milk. He wished to point out that there was an alternative to this which had been found to be very successful in those districts in which it had received adequate support—namely, the production of Grade A tuberculin tested milk, the price of which was very much less than that of certified milk. In the town of Reading this milk formed not less than one-sixth of the total supply of the town, was sold without treatment, and was purchased by the poor in quantities at least equal to those which were purchased by the rich.

Dr C. A. MORTIMER-BROWN (Brampton) called attention to the need for a clean water supply and an incubator on dairy farms.

Mr WILFRED BUCKLEY, in reply, said that he proposed in future to test his cattle for tuberculosis—once by the subcutaneous method and once by the intradermal. He pointed out that under the new Tuberculosis Order the farmer was to be compensated for under disease and emaciation instead of being fined or imprisoned. It was not possible to eliminate or isolate all tuberculous cattle. In this country there were about 2,500,000 milch cows, where were the 1,000,000 reactors to be put? In matters such as this it was advisable to go reasonably slowly. The percentage of fat in milk could be kept within a limit of variation of 1/2 per cent if cows could be milked every twelve hours, but conditions of transport and so on

did not allow of this. In Mr Buckley's opinion more suffering was caused by tuberculosis than by other diseases, but some said that there was more disease from dirt. He protested strongly against the view of some physicians that children could be immunized against tuberculosis by consuming tuberculous milk. It was a view which encouraged bad producers.

Mr MAGGS was not satisfied with the present state of things. The farmer already helped to eliminate cows by sending them to the butcher, and if Mr Coleman had not condemned the 164 cows in 1913, the farmer would have condemned them himself. Inspection might be adequate in Liverpool, but this was not so in other places; in many places it was a farce. Consequently he was not impressed by Mr Quinton's views on legislation, and he asked if there had ever been a prosecution for dirty milk in London.

The CHAIRMAN said that the medical profession must stimulate public interest and a public demand. Education was needed both amongst the public and in the medical profession. He disliked the division of milk into grades, as he thought that under ideal conditions the term "milk" should be sufficient. The producer must be able to assure the medical man that his goods would be up to standard. Dr Flemming wished to add another slogan to that mentioned by Mr Maggs about the doctor—namely, "Dirt in the cup Will send his bill up."

At the end of the afternoon session a visit was paid to the fifteenth century moated manor-house at Great Chirfield, where a demonstration was given of the production of Grade A certified milk.

THE TREATMENT OF HARE-LIP

BY

HENRY F. MACAULEY, M.B., M.Ch., F.R.C.S.I.,
SURGEON THE CHILDREN'S HOSPITAL, TEMPLE STREET, DUBLIN
ST. MARY'S OPEN AIR HOSPITAL, CAPPAIGH, ETC.

As many improvements which have been introduced into the operations for the repair of hare-lip—or cleft lip as Brophy¹ suggests it is more correctly designated—have not yet found their way into the ordinary textbooks, it has seemed worth while to give an account of those that I have found useful.

The age of choice is about 3 months; this can be varied, but it should be remembered that the longer the operation is postponed the larger the cleft becomes. The infant ought to be fed until about two hours before being given the anæsthetic, which should be open ether reinforced subsequently, if necessary, by a few whiffs of chloroform through a Junker's inhaler. I prefer to have the patient upright on the table with the head supported from behind by a nurse. This prevents the reflux of blood into the pharynx, and avoids pulmonary complications.

Simple, Single Cleft Lip

After cleansing the operative field, two stout silk sutures are passed on a curved needle from without inwards and half-way up the lip near each angle of the mouth, they are tied with a good deal of tension.² Good hæmostasis is secured by this method, and if the free ends of the sutures are caught in forceps they will act as efficient retractors. Special forceps are advocated for the purpose, but in my opinion are inferior to the silk ligatures. The lip and cheek on each side of the cleft is freed from the underlying bone in the usual way; the extent to which this is carried depends on the size of the cleft; it is particularly necessary to free and bring down an abnormally attached ala nasi.

The next step is to pare the sides of the cleft. Each side of the cleft is incised from the upper end down to the exact line of junction of skin and mucous membrane on the lip margin. The incision separates the red margin of each side of the cleft, and in addition a small triangular area of skin with each. It is essential that the flap be not

too slender, as the lip will be liable to part later at the sutured area, or too thick, for then the upper lip will be too narrow, and subsequently the lower lip will project. It is for the latter reason that I abandoned the use of Thompson's lines, for though they gave a beautiful result in the repaired lip, they caused the sacrifice of too much lip tissue, and when the child was seen after a year or so the lower lip was unduly prominent.

The tips of the free ends of the detached flaps are caught in a pair of Allis's tissue forceps, which will serve to control the flaps and to approximate the raw margins for suturing (Fig. 1). It is to be noticed that so far no tissue has been sacrificed, the flaps having been turned down in their entirety; this is Mayo's method.³ Suturing is now proceeded with, fine silk-worm gut or horsehair on the skin, and catgut on the mucous membrane side, to close the raw area there and prevent adhesion of the lip to the cheek. The first suture should be through the skin, emerging exactly at the line of the mucocutaneous junction on either side of the cleft, the accurate approximation of this line is of the utmost importance. The second suture is placed at the upper end of the cleft, and it should also be finely adjusted in order to secure a good nostril.

Then when all the suturing is finished except at the free margin the excess of tissue is removed from the flaps by an oblique incision, and the free border of the lip is finished by a mattress stitch of catgut. The small triangles of skin turned down in each flap are removed by the incision together with excess of mucous membrane. A little excess of tissue is left at the free margin, this by Mayo's method is rendered very easy.

The operation described above is for complete single clefts, for incomplete clefts the steps are much the same, but freeing of the cheek from the bone need not be so extensive, and the incisions for the flaps commence above the angle of the cleft, and need not go into the nostril.

FIG. 1.—Showing hæmostatic ligatures. The dotted lines show excess of tissue to be removed after suture of the skin edges.

Cleft Lip with Unilateral Detachment of Premaxilla

If the lip can be repaired without interference with the premaxilla, that bone should not be touched, as in the course of time pressure of the repaired lip will put back the prominent bone into good line. If, however, the prominence is so marked that the lip cannot be repaired over it or only repaired with considerable tension, then the bone requires replacement. It is, I think, useless to attempt to push the bone back into place unless it is fractured at one end. Various methods of producing the fracture are suggested, probably the following are the best.

Method A—Make a small incision on the alveolar edge where the interval between the lateral incisor and canine on the attached side of the premaxilla would be expected to be there insert a small chisel and fracture the bone sufficiently to allow manual replacement.

Method B—This method was originated by Mr. Staunton in the Children's Hospital, Dublin, to produce a fracture of the site mentioned and leave the overlying mucous membrane intact. A specially devised forceps is used, one blade of which is broad and blunt while the other has a narrower but blunt edge. The forceps is so made that the blades on full compression do not meet but sufficient space is left to allow the more elastic soft parts to escape whilst the mella bone is fractured.

The usual procedure when the bone has been mobilized sufficiently is to pierce the edges of the cleft alveolus on either side and to fix the bone by wiring across the cleft. This method is to be condemned as it is unnecessary and difficult in performing the bone for the wire teeth on each side of the cleft are often destroyed or detached, and the wire often cuts through, or a piece of the premaxilla may be detached. It is much better to proceed immediately to do the lip operation, as the repaired lip will then act as an efficient splint.

Cleft Lip with Bilateral Detachment of Premaxilla

This constitutes the most difficult problem in the surgery of the condition, as the bone is frequently displaced far forwards its reduction and retention in place may be extremely difficult. Of course if the displacement of the bone is slight it may be possible to bring the lip over it without interfering otherwise with the bone. This fortunate state of affairs, however, is very unusual, and other methods are generally necessary.

The anterior part of the nasal septum, to which alone the projection is attached, must be divided by making a short incision along the lower edge of the nasal septum right down to the bone, separating the soft tissues from the underlying bone, and dividing the denuded septum for the required extent with a small stout pair of scissors.

In these cases it is practically impossible to avoid retention wire sutures to hold the mobilized bone in place. For this purpose as the premaxillary segment is so small, I have devised a method in which it is necessary only to pierce that segment once, and only in its central thicker part. The best instrument to use for piercing the bone is a very small sized trocar and cannula the cannula being without a shoulder so that it can be with drawn through the bone either outwards or inwards. For ease of insertion and avoidance of undue trauma to the small premaxillary segment, I strongly advise piercing and insertion of the wire through that segment before it has been mobilized by division of the septum. The bone is pierced at its centre by the trocar with cannula attached and the trocar is withdrawn and the two free ends of a silver wire loop are

FIG. 2.—Horizontal view showing method of wiring premaxillary segment in bilateral detachment.

passed from within (from the mouth cavity) outwards, leaving the loop on the inside. Each free end is then drawn in an opposite direction. The superior maxilla of each side is pierced at some distance from either cleft as before and each free end is returned through the cannula to project on the inside of the mouth. The margins of the cleft are pierced, and the suture tightened by drawing the free ends through the loop, pulling them taut, twisting the wire and cutting off any excess (Fig. 2).

The lip may be repaired immediately, or if the ability of the child to stand further operation at the time is questionable, further measures may be delayed for some days.

The repair of the lip defect is carried out as before. The fleshy middle part of the lip attached to the premaxilla is merely freshened by two perpendicular cuts down the sides, and from then lower ends by two angular cuts meeting at the midpoint of the lower border. Mayo's flap method is employed on the lateral margins of the cleft. Sutures are then carried out but there is no excess of tissue to be removed. It may be necessary to make lateral cuts into the lip tissue on either side before suturing, to secure accurate coaptation of the lateral with the central fleshy segment and to give fullness to the lip. As even with the premaxilla replaced it is sometimes difficult to avoid tension, it is useful to remember the suggestion of Gosselin in such cases, to do only the repair of one side of the double cleft at the time and at a subsequent operation, when the wound has completely healed, to do the other side.

Post-operative Treatment

The silk haemostatic sutures at the angles of the mouth are removed immediately on the completion of the operation. The question of fixation of the cheeks by drawing them towards the middle line so as to avoid strain on the suture line has then to be decided. In the majority of my own cases I merely paint the wound with ichthyl, leave it without covering of any sort, and I use no fixative whatever. But if a child is very fractious, and particularly in cases of bilateral clefts, I adopt one of two methods of fixation. The first, by passing two pieces of a sterile plaster, one from the cheek in front of the ear up over the bridge of the nose and down to a corresponding point on the other cheek, the cheeks meanwhile being drawn inwards, and the other from in front of the ear down to the chin and up to a corresponding point on the other side, to exert the lip and allow a free inward as well as to aid in relieving tension. The other method also leaves the wound free. It is the use of the Langan traction brace as depicted in Brophy's textbook.

The trend of modern methods in the treatment of the deformity of cleft lip is to use simple methods for the repair of the lip and to avoid when at all possible, interference with associated lesions of the alveolus.

THE USES OF COELIOSCOPY

BY

A. RENDLE SHORT, M.D., B.S., B.Sc., F.R.C.S.,
SURGEON TO THE BRISTOL ROYAL INFIRMARY

An exploratory laparotomy, often referred to as though it were a mere trifle, may be from the patient's point of view a very formidable affair. It involves a general anaesthetic followed probably by some flatulent discomfort and perhaps anaesthetic vomiting and two or three weeks in bed and occasionally some complications with the wound. The expense may be considerable. In cases of enlargement of the stomach, or malignant processes, death may follow so soon after as to raise a suspicion that the operation had something to do with it.

In a certain number of cases, not many perhaps, there is a far less formidable alternative. This is to distend the abdomen with air, which can be done without serious discomfort under a local anaesthetic through a tiny incision, and to inspect the viscera with a cystoscope. I have been using this method for about a year, and have never seen him follow. Like every other technical procedure, a little trouble must be taken to learn how to get a good view, but it is not more difficult than cystoscopy.

The advantages of coelioscopy over exploratory laparotomy are (1) it can be done without discomfort under novocain, (2) the incision is so small that it is only necessary to keep the patient in bed for a day or two, (3) no special instruments are needed, (4) it can be done at the patient's own house, (5) it is available when it would be dangerous to perform laparotomy.

A few examples may be given to illustrate its usefulness. Small malignant nodules have several times been seen on

the surface of the liver, which in one case clinched an uncertain diagnosis, and in another forbade a drastic operation. In a case in which tuberculous peritonitis was suspected it was easy to see that there were no tubercles on the intestine. The extent of a carcinoma on the surface of the stomach may be discerned. Information may be given as to the nature of swellings of uncertain origin inside the abdomen. I have once or twice seen the appendix presenting itself. Pelvic tumours can be suspected. The method would be available to determine the presence or absence of blood in the abdomen in cases of ruptured ectopic gestation or traumatic rupture of a

FIG 1—Coils of normal small intestine.

viscus. It is easy to see whether the liver is or is not "hobnail."

Coechoscopy does not and cannot replace exploratory laparotomy in those cases where the cause may have to be sought for and does not lie on the surface of the abdominal viscera, and these will always be the majority. It is principally valuable for what is definitely seen, and not for what is apparently absent.

The technique is simple. Under novocain anaesthesia, or under ether if preferred, an incision half an inch long is made in the skin and fascia. I usually enter in the middle line just below the umbilicus. Above the umbilicus difficulties with the falciform ligament arise. Liver after

layer is picked up with a pair of artery forceps until the peritoneum is opened, the incision being just as large as will admit the cystoscope, but no larger. The cystoscope, sterilized in carbolic solution, is then passed in and the abdomen inflated with air through it. The air is filtered through sterile wool, and an ordinary bellows is all that is necessary. Then the lamp is inserted, the brightest possible light is used. Some risk of fusing the bulb must be run. If the upper abdomen is to be examined the table is tilted to raise the head, and vice versa. I usually commence by finding the edge of the liver on the right side, and then the gall bladder. If the patient is under a local

FIG 2—The edge of the liver showing a small nodule of carcinoma on its surface.

anaesthetic the peristaltic movements of the small intestine can be seen. When the examination is finished, the air is let out as completely as possible and a stitch put in—unless, of course, the findings are such as to encourage a set operation.

Fig 1 shows coils of normal small intestine, and Fig 2 the edge of the liver, with fat lying on the surface of the viscera below it. There is a small nodule of carcinoma on the surface of the liver, secondary to a growth in the rectum, no operation, therefore, could be undertaken. I am indebted to Mr. Sewell for the pictures. They are from two separate cases.

MEDICAL, SURGICAL, OBSTETRICAL

PARALDEHYDE POISONING

PARALDEHYDE is not a scheduled poison, but is used extensively as a sedative in mental cases. There are only two cases recorded of death from this drug, one of them being a person suffering from typhoid fever. A recent case (Liverpool, June, 1925) is interesting and should be put on record.

The person was a man aged 41, very lightly built, who had been accustomed for some months to take doses of paraldehyde varying from one to two teaspoonfuls. The source of his supply of the drug up to the present has not been ascertained and it is probable he had gradually increased the dose. On the last occasion he went to bed at 11 p.m. and slept by himself. The next morning at 8 o'clock he was found dead in bed, a glass with half an ounce of paraldehyde and a 4 ounce bottle containing three-quarters of an ounce of paraldehyde were by the bedside, two other empty 8 ounce bottles were in the room. The washings gave the reactions of paraldehyde. It is estimated that he had taken between 2½ and 3 ounces. He had had very little food of any kind and very little stimulant for two or three days before death. When found there was a little oozing of stained fluid from the nose but no vomiting had taken place.

At the post mortem examination the innermost exposed portions of the lips were seen to be dry and darker than normal, the mouth smelt of paraldehyde. The mucous membrane of the mouth, epiglottis, larynx and upper portion of the oesophagus were blanched and in the lower third of the oesophagus the mucous membrane bore light-coloured coagulated patches.

On opening the body the cavities smelt strongly of paraldehyde. The stomach, normal in size, contained about 5 ounces of turbid fluid smelling strongly of and giving the reaction for paraldehyde. The mucous membrane was marked hyperaemic with

uniform injection of the small vessels. The hyperaemia was more marked on the back part of the stomach towards the cardiac end. The mucous membrane of the duodenum was more lightly injected, the appearance gradually fading away, the small and large bowels and their contents were normal.

Both lungs were very congested at the bases. The blood was fluid and dark. The heart showed some small atheromatous patches on the aorta just beyond the aortic valves and at the openings of both coronary arteries it was otherwise normal. The liver, spleen, kidneys and brain were quite normal. All the organs seemed to bear the odour of paraldehyde but it was difficult to eliminate the smell. The bladder contained 14 ounces of urine which smelt very strongly of paraldehyde and gave the chemical tests for aldehyde.

As the deceased had made his ordinary arrangements and laid out his clothing ready to be put on the next day, the case was taken and returned as one of misadventure.

RAT-BITE FEVER IN AN INFANT

As rat-bite fever though common in Japan, is rare in England, the following case, which occurred recently in Sunderland, seems worthy of record.

On April 8th an infant was bitten on the right thumb while in bed with its mother, the wound bled profusely. Next day the thumb was somewhat swollen and dark in colour, the back of the hand was also swollen. The child had some bronchitis and appeared ill. During the ensuing week the swelling subsided, the wound healed and the general symptoms abated. Fifteen days after the bite a scarlatiniform rash appeared about the chest and armpits, together with four swellings, one on each wrist and one just below the sternal end of each clavicle. There was some pyrexia. The child was taken to the Borough Sanatorium and next day the swellings were incised, thick pus being evacuated. This was placed in broth and some blood smears forwarded to the pathologist. Dr

Cookson, who reported polymorphonuclear leucocytosis, and isolated a leptothrix from the culture. Four weeks later a further abscess formed on the right wrist. To date there have been three periods of three day pyrexia of intermittent type, and the patient has now been discharged well.

It is interesting to note that the mother was bitten on the head previously. The rat was caught on the night after it had bitten the child, but was not obtained, half having been eaten by a cat and the other half thrown away. It was reported that the rat suffered from salivation and was off its feeds at the time the abscesses appeared on the child, but we were unable to gain possession of the animal.

JUSTICE THOM,
Assistant Medical Officer of Health, Sunderland.

FULL TIME PREGNANCY IN A BICORNUATE UTERUS

THE rarity of this condition is sufficient justification for recording the following case. I have not seen a pregnancy in a bicornuate uterus myself in twenty years of active practice, during which I have averaged 100 confinements annually.

At 10 p.m. on May 2nd I was called to see a primipara, aged 28, in the first stage of labour. I had not seen her previously, and on arrival found a woman of delicate appearance somewhat anæmic and with a history of headaches for the previous week. She admitted one finger the presentation was left occipito-anterior. The appearance of the abdomen was unusual. There was a distinct longitudinal tumour occupying the left half of the uterus which gave the impression of being thickened uterine muscle rather than uterine contents.

She was delivered spontaneously at midday on May 3rd of a male child weighing 6½ lb. After waiting one and a half hours with no sign of separation of the placenta and as the perineum required repair I anaesthetized the patient and intrauterine examination. I found that the uterus was completely divided by a well formed muscular septum, and after difficulty removed from the fundus of the right compartment an extremely adherent placenta. I was able to introduce three fingers without difficulty into the left compartment of the uterus.

Except that the lochia was very profuse for the first week she made an uninterrupted recovery.

MENINGITIS AND KERNIG'S SIGN

It does not seem to be generally known that meningitis may occur in young children without its characteristic signs. A few months ago I saw an infant, 3 months old, which had a temperature of 104° and convulsions, but there was no retraction of the neck, no Kernig's sign, and no bulging of the fontanelles, yet, by a lumbar puncture, I drew off cloudy fluid, a direct film from which showed very numerous meningococci and polymuclear cells.

In my experience it is unusual to get retraction of the neck and Kernig's sign in meningitis in a child under a year old, and up to 3 years of age meningitis may be present without these signs, but I have never seen them absent in children over 3 years. By retraction of the neck I mean inability to make the chin touch the chest without pain. This retraction of the neck and Kernig's sign may be found where there is not meningitis, the cerebrospinal fluid is under pressure if lumbar puncture be done, but clear and normal on examination. This is often found when a mastoid operation has been delayed or incompletely performed, and it is then an indication that the inflammation in the bone is approaching the meninges and will soon cause a genuine meningitis.

I have also seen this meningismus in a bad attack of typhoid fever in a child of 6, whose temperature was 105°. The child made a good recovery without any real meningitis. In severe pneumonia in young people retraction of the neck and Kernig's sign may be found when the fluid drawn by lumbar puncture is clear and normal, and pneumococcal meningitis does not follow. In sunstroke these signs of intracranial pressure may be marked, and lumbar puncture greatly improved the patient's condition in two cases that I have seen. Other conditions in which retraction and Kernig's sign are sometimes found are encephalitis, lethargia, tumour of the brain, especially near the base, large cerebral hæmorrhages and in uræmia when headache is severe or convulsions are threatening.

MEDICO-PSYCHOLOGICAL ASSOCIATION

The annual meeting of the Medico-Psychological Association of Great Britain and Ireland was held at the University of Birmingham on July 6th to 10th, under the presidency of Sir ILMERICK MORT, who announced that the Council had nominated Lieut.-Colonel J. R. LORR, Editor of the *Journal of Mental Science*, to be the next President. The meeting closed in silence, resolutions of condolence on the deaths of Sir Clifford Allbutt and Dr. Rouse.

The Sympathetic Endocrine System

Dr. DAVID ORR of Prestwich Asylum gave a lantern demonstration on the sympathetic endocrine system. He said that emotion and all intellectual life were inseparable from and depended on sensory stimuli, from birth until and beyond adult age. Certain areas of the brain were associated with the registration of visceral impressions, and there was no impression in any part of the body which was not registered in the brain and which did not immediately react on certain organs. The central nervous system could not be spoken of as a system *per se*, it was intimately connected with the sympathetic system, and this latter with the ductless glands. He referred to CRYSLER's laws, one of which was that of dynamic polarization—namely, that in axis cylinders spread its little collaterals around the protoplasmic processes of the cell, when an impulse passing through it was then transmitted into a multitude of cells. As every impression reached the brain it was accompanied not only by its own specific sense, but by an emotional content, and it aroused certain responses, it produced either a pleasant or an unpleasant sensation, as there was no such thing in the human mind as a negative impression. Through the spinal cord impressions were going down, they then spread through the interior roots and into the white ram of the sympathetic system, and thence onwards. All this time sensory impressions were proceeding up from the viscera, and from the ductless glands, forming reflexes. The vegetative system possessed its reflexes, as did the system which was related to the outside world. This was most important, and was a standing justification of the treatment of mental patients from the physical point of view. Dr. ORR proceeded to elaborate his thesis, and demonstrated the sequence of events during a nervous upset. His main point was the intimate co-operative working of the whole mechanism and the need for treating patients from the physiological point of view.

The President's Address

SIR FREDERICK MORT, in his presidential address, said that no progress was possible in knowledge of mental disease until the spell of metaphysical speculation had been shaken off, since that carried with it the doctrine of mind as an invisible intangible spirit with its existence separate from the body. The functions of mind depended on the whole body and on the harmonious action of all its parts. In the apparently healthy brain there might be subtle biochemical and biophysical conditions which were dependent on inborn functional or bodily defects. Acting on the highest levels of the brain, small doses of narcotics sufficed to affect intelligence, self-criticism, judgement, and control, leaving the lower levels unaffected, the higher levels were the first to undergo the deleterious effects of any form of intoxication. This highest level represented the psychic personality of the individual, and was the personal equation due to inborn tendencies and characters derived from racial and familial ancestry, near and remote. Primitive people suffered from the same psychoses and psycho-neuroses as did the most cultured people, but the illusions, hallucinations, and delusions were coloured by social usages, customs, and beliefs. Yet there might be no discovered differences in the brain structure, even by powerful microscopy. There might be a vital germinal deficiency, perhaps manifesting itself by an arrest of development of many of the cortical neurons or a lack of durability. Vascular conditions might

be present which interfered with the nutrition of the rapidly developing neurons.

Sir Frederick Mott then proceeded to deal with the changes in the mental attitude coincident with the involutional period—adulthood—remarking that all psychic activities were subordinate to and dependent upon physiological processes. Indeed, he put forward the premise that a disintegration of the psychic unity might be conditioned by a disintegration of the physiological unity. The functional correlation of mind and body was shown by the profound influence which the reproductive endocrine system exerted upon evolution at puberty and on the sentiments which had their roots in the sex instinct. In the female particularly, the repression of this instinct caused a mental conflict, which might end in neurosis or psychosis, hence it was not surprising that disappointed love was fairly frequently assigned as a cause of mental breakdown. The function of reproduction stood in a position different from that of any other—it depended not alone on the sex organs, but also on the functionally correlated endocrine system of glands. Steinach had shown that the substances of internal secretion had a selective action in storage in the central nervous system, and it was not sufficiently recognized that a characteristic might occur in men between 55 and 65 years of age, being observed in some of them—but not in all—with arteriosclerosis. Some cases of involutionary melancholia had their origin in testicular regression and the concomitant endocrine gland changes, for in many such persons the *potestas* had ceased.

The President next dealt with inborn characters of mind. A high degree of mental plasticity was, he said, necessarily associated with an enhanced liability to mental instability, and this even more than intermarriage, was responsible for a high percentage of the cases of psycho-neurosis and psychoses in the Jewish race. A study of relatives in a large series of cases in the London county asylums revealed three main facts in relation to the causation of mental disease: (1) the importance of a neuropathic and psychopathic heredity, (2) the special liability of the neuroses and psychoses to occur in adolescence, and (3) the influence of child bearing and lactation in women, acting as an exciting cause. Speaking of alcohol, he said this normalized the highest volitional level, and it was a source of benefit in banishing anxiety and sorrow until the morrow, but it must be retained as the servant and not allowed to become master. In most of the cases diagnosed as dementia praecox there was found to be a regressive atrophy of the reproductive organs, of the pituitary and the adrenal glands. The general conclusion he wished to enforce was that it was the duty of medico-psychologists to practise general medicine in its broadest sense, and to ascertain whether there was present any body condition which could act either as a cause or a contributory factor in the production of the abnormal psychic state.

Encephalitis Lethargica: Its Psychological Implications

Dr G. A. ARDEN pointed out that the late sequelae of lethargic encephalitis gave it sinister importance, which was intensified by the steep rise in the epidemic incidence which had marked the past year. Lethargic encephalitis opened up an entirely new outlook in psychiatry and neurology, which might bring us to a better understanding of the genesis of certain psychoses and neuroses. Confining his remarks to children between 5 and 15 years of age, he pointed out that the clinical picture presented by the disease was one of a generalized toxic condition, which affected particularly the nervous system, while the later manifestations both psychic and somatic, formed a syndrome which gave all the features of a definite and distinct morbid entity. One of these was a characteristic failure of adjustment to the inhibition and sanctions of the social order, especially in the direction of persistent thieving and lying. Other features such as a reversal of the normal sleep rhythm, coupled with noisy excitability, perverse habits such as that of tearing the clothes to pieces, seemed to bring the disease into definite relationship with certain types of mental disorder. A considerable number of children developed peculiar habits and ties. Some of these might be attributed in the first instance

to increased suggestibility—thus, the hawking and spitting might be the result of a salivation which had passed off. Occasionally cases showed iteration compulsions. In some of the advanced cases of Parkinsonism there was a superficial resemblance to catatonics, but in these cases as von Leonono had pointed out the patients were appreciatively and intellectually intact, appreciating fully their relation to their environment, well orientated, and with undiminished critical judgement. The main characteristics were a combination of mental apathy with explosive irritability, a rapid onset of fatigue and a marked drop in attention, with a heightened susceptibility to emotional stress. These might be correlated with an inhibition of volition and a failure of the exercise of self-criticism. In the opinion of Dr Arden the theory of the development of the nervous system put forward by Head and Rivers gave a key to the proper understanding of these characteristic changes and volitional defects. They appeared to be regressions due to a removal or suppression of the epiepic control over the protopituitic instinctive tendencies. The child was essentially, in Lloyd Morgan's phrase, a "self of enjoyment," and it was only as he grew that the ceaseless stream of suggestions of social import raised in him a predisposition towards social conduct. This process of regression might be compared to the geological process of denudation, whereby the newer sedimentary formations were removed, leaving bare the ancient and primitive rocks upon which they had been deposited. This view received confirmation from the action of alcohol on emotions, the effect being to produce a regression to a more primitive all-or-none protopituitic type of reaction. With regard to treatment, if the theory set forth in the paper was correct punishment could have little or no deterrent effect; indeed, it might have disastrous results by fixing an antisocial attitude through the creation of a conflict or an inferiority complex. Under the simple and regulated life of a special institution, differing from the Boarding or industrial school type, sufferers from encephalitis lethargica would reacquire the necessary epiepic control to enable them again to take their places in ordinary life.

Chronic Infective Processes in Mental Disorder

Dr I. C. GRIVES (medical superintendent, Holloway Asylum), in an elaborate paper on the incidence of chronic infective processes in association with mental disorder, said that often the conditions found were beyond the possibility of cure as they were slow, insidious, and hidden, and sometimes they had not given evidence of their presence. The infective process might be deep in the jaw-bone, and a sequel to this might be a chronic osteomyelitis. In the femur the motor and sensory disturbances were usually intensified at the extremities and especially at the premenstrual phase. He narrated a number of cases in which slides of the dental conditions were shown and the clinical notes read out. In some cases after extraction of teeth a root had been left, and the shutting in of infection had led to spread into the bone. Some people with undoubted septic foci seemed not to suffer disability from them, the explanation being that they were putting up an effective resistance. He also dealt with the questions of sinus infection, infection of the tongue, tonsils, and, in the female, the genital tract and contended that these septic processes played a definite part in the causation and the duration of mental disorder.

Delinquency

Dr W. A. POTTS, in a contribution on delinquency, said he thought the time would come when all sexual offenders, those of a kind now sent to reform homes and those who had committed serious offences, would be referred for a special medical examination. Inability to earn a living might be due to lack of training or a definite handicap. Activity simply to obtain luxuries, denoted a wrong attitude towards life. The first duty was to see that the person concerned was not suffering from a physical or psychological handicap, the latter being divisible into inborn and environmental. The presence of a physical disability did not mean that there was not a psychic one also, but when a physical factor had been efficiently dealt with the

psychological factor disappeared of this he quoted some convincing examples. But children must not be trusted until they were old enough or had been trained enough for this. Defective sight was important, for if a boy could not see everything on the board at school, he was weighed down by a sense of inferiority. In many cases of juvenile delinquency the problem was the parents. It had been said that 10 per cent of delinquents were mentally defective, but Dr Potts regarded this figure as much too high, it was nearer 2 per cent. A very useful point to determine was the mental age of an offender in comparison with his actual age in years. A mental conflict must be recognized and treated as such usually the delinquent was failing along more than one line. He had found that homosexual offenders had been retarded, especially on the emotional side, and that they responded well to psychoanalysis. Cases of chronic alcoholism required much more serious attention than had been yet devoted to them by the profession, and the possible benefit from treatment was better than was generally realized. Physical treatment should not be neglected, and here also psychoanalysis was valuable.

Iodine Content of Thyroid Glands

Dr F A PICKWORTH read a paper which represented a further stage of the work by Sir Frederick Mott that had been submitted to the association at its meeting in Belfast last year. An attempt had been made to correlate the iodine content of the thyroid gland with histological structure, and the mental and bodily condition of the patient. Patients with myxoedema and those who had very sluggish thought were greatly benefited by the administration of thyroid gland, no other form of treatment having any effect. Dr Pickworth described and demonstrated his new method of ascertaining the iodine content of glands. It consisted of the destruction of the organic matter by fusion with alkali, and the oxidation of the resulting iodide to iodate with permanganate solution, the excess of the latter being removed by means of animal charcoal. After filtering, potassium iodide was added, and the iodine titrated with thiosulphate solution. Arterio-sclerotic glands showed less iodine, and in fibrotic glands the iodine was very low indeed. A case of tuberculosis showed a lowered iodine content, but one of primary tuberculosis showed iodine above the normal. A low quantity of iodine was also found in melancholia, mania, dementia praecox, and arterio-sclerosis, as well as in dementia. In the thirty-nine cases of general paralysis of the insane there was a large range of variation in this respect. It became clear from this investigation of over a hundred cases that the iodine content in the thyroid was very important in combating infections, though it probably was associated in this influence with the endocrine products.

Institutional Treatment of Mental Defectives

Dr A M McCUTCHON read a paper on the treatment of mental defectives, with special reference to occupational training. He said the objects of this treatment in institutions were four: (1) to correct antisocial conduct, (2) to restore self-respect and happiness, (3) to teach the patients the work for which they seemed most fitted, leading to discharge if possible, and (4) by stopping the procreation of children to prevent the blight from being handed on. All these could best be achieved, he thought, by segregating them in institutions, preferably of the colony type. A keynote of success was adequate classification. He discussed the question from the standpoints of the child and the adult, and ended by an examination of the question of reversion.

The Psychopathic Personality

Dr HAMILTON SMITH (medical officer of the Birmingham Prison) said that the cases of psychopathic personality formed a large but ill-defined group, the members of which found it impossible to make satisfactory social adjustments. They had a strong inferiority complex, and however well the physical treatment of them might be carried out the psychiatric must not be neglected. The abnormal degree of worry which they seemed to experience was not so much a reaction to an environmental state as a reaction to something in the patient's unconscious mind. These people had a 'shut-in' personality, and the hope for the future lay in taking the psychological view of them.

Rebicus.

THE RACES OF MAN

THIS book, *The Races of Man and their Distribution*,¹ though small in size, is pregnant with the learnings of a lifetime. It is written by the most outstanding figure among British anthropologists, Dr A C HADDON, Reader in Ethnology in the University of Cambridge. Thirty-seven years ago, when Professor of Zoology in the Royal College of Science, Dublin, Dr Haddon went to study corals in the Torres Strait. When there he realized that coral zoophytes might be investigated in any subsequent century, but that if the native races in that part of the world were to be studied investigations must be set on foot forthwith, for natives and native modes of living were disappearing under the drive of Western civilization. At great and continued personal sacrifice he devoted his life to this mission, and by his own efforts, ably seconded by those of his distinguished pupils, has made the British school of anthropology respected at home and renowned abroad. Dr Haddon reached his 70th birthday this year, and his many pupils and admirers gladly seized the opportunity to have his portrait painted by a distinguished artist as an acknowledgment of the services he had rendered to anthropology and of the love and esteem in which they hold him.

Thus it is scarcely necessary to say that this new work by Dr Haddon will prove of the highest service to all who study, or are interested in, the racial differentiation of mankind. It is true that Dr Haddon issued a small book on the races of man sixteen years ago, but so much has happened since then, so much has been learned that is new, that the present work, although described as a new edition, is really a new book. For its author has been not only a student of culture but also of race, and has been engaged for many years in collecting data concerning the origin and distribution of the races of mankind, with the view of preparing a standard treatise. The book now issued is a summary of the proposed larger work.

The main feature of the present book is the theory put forward by the author to account for the distribution of living races of mankind which are rightly regarded as products of a common stock. This stock, on the author's theory, is regarded as having been evolved in Central Asia, the Himalayan range being presumed to have been a primary dividing line. All the finer races have been evolved to the north of this primary racial watershed, while the darker have come into being in lands to the south. By adopting such a hypothesis Dr Haddon believes that a rational explanation can be given of the distribution of living races—at least their distribution before the overseas exodus set in from Europe. The subject is one which appeals to many medical men, and to such this work by Dr Haddon can be recommended unreservedly.

HUGHLINGS JACKSON'S "NEUROLOGICAL FRAGMENTS"

THE volume of the late Dr J HUGHLINGS JACKSON'S *Neurological Fragments*, edited by his pupil Dr JAMES TAYLOR, is sure of an enthusiastic welcome by neurologists and should interest all medical men, not only on account of the collection of the twenty-one fragments which appeared from 1893 to 1909, described by Dr James Taylor as illustrations of intensive neurological investigation and research, but because of the personal features of the character of this philosophic neurologist contained in Dr Taylor's memoir and the biographical recollections of the late Sir Jonathan Hutchinson and the late Dr Charles Macleer. Hughlings Jackson was persuaded not to give up medicine for philosophy by his lifelong friend Jonathan Hutchinson, who, however, later had misgivings whether

¹ *The Races of Man and their Distribution*. By A C Haddon. Second Edition. New edition. Cambridge: The University Press, 1924. (Cr. 8vo. pp. viii + 184. 10 plates. 6s. net.)
Neurological Fragments. By J. Hughlings Jackson, M.D. F.R.S. F.R.C.P., with a Biographical Memoir by James Taylor, M.D. F.R.C.P., and including the Recollections of the late Sir Jonathan Hutchinson and the late Dr Charles Macleer. Oxford Medical Publication. London: H. Milford Oxford University Press, 1925. (Demy. 8vo. pp. ix + 227, 1 plate. 12s. 6d. net.)

it would not have been a greater gain to the world at large if philosophy had had the advantage of his undivided devotion. His characteristics are admirably described, and it is interesting to be told that with all his perfect courtesy he had much in common with Samuel Johnson, whom he greatly admired and often quoted. They were both conservative, with the same power of brushing aside subtleties so as to get to the very essence of the matter, had the like contempt for pretension and the same love for the real truth, many of Jackson's utterances were quite in the Johnsonian vein. He said of Gilbert White of Selborne that he "Boswellized the birds, he took down the familiar conversation of Nature."

A Yorkshireman by birth, Hughlings Jackson was house-surgeon to the York Dispensary when Dr Thomas Laycock, who was much interested in the relations of the nervous system to psychological phenomena, was physician before his election to the chair of physics at Edinburgh, the first Englishman to obtain this coveted post. On coming to London he met his fellow Yorkshireman Jonathan Hutchinson, and the two undertook journalistic work in general medicine until the influence of that erratic genius, Brown-Sequard, caused Jackson to focus his energies on the nervous system. The late Dr Charles Mercier held that no man ever had a better right to the title genius, and that his speculations on the ultimate nature of mental processes and their connexion with brain processes would undoubtedly be the foundation of a future system of psychology, he rather characteristically remarks that Sir Andrew Clark's dictum that neither Jonathan Hutchinson nor Hughlings Jackson had a sense of humour is accountable only when we remember that Sir Andrew was a Scotsman.

The neurological fragments were preceded in time (1892) by a lecture bearing that title, and as this apparently suggested the series of shorter articles which commenced in the following year it has appropriately been inserted in this volume. In addition there is a useful list of Hughlings Jackson's published articles from 1861 to 1909—about 284 in number.

In conclusion it may be said that this most interesting volume is a welcome complement to the Hughlings Jackson number of *Brain* (1907, vol. 425-311), which celebrated his jubilee in medical practice, to the late Dr G. Schorstein's article in the *London Hospital Gazette* (October 1895) in connexion with the presentation portrait of Dr Hughlings Jackson, and to the complete account of his views and writings on speech defects contributed by Dr Henry Head to *Brain* (1915-16, vol. 1, 1-90).

A MANUAL OF COMMON INFECTIOUS DISEASES

Dr FREDERIC H. THOMSON'S little work on *The Diagnosis and Treatment of the Infectious Diseases*³ is based on thirty-four years' experience of infectious diseases in the service of the Metropolitan Asylums Board. During more than half of that period the author had given courses of postgraduate lectures. The book is divided into thirteen chapters, the first dealing with the conveyance of infection, while the remainder are devoted to a consideration of thirteen diseases—namely, measles, rubella, scarlet fever, small-pox, chicken-pox, enteric fever, typhus, diphtheria, cerebro-spinal fever, acute poliomyelitis, lethargic encephalitis, whooping-cough, and mumps. Dr Thomson's long experience entitles him to speak with authority, and many of his readers will regret that he has not embraced the whole subject of infectious diseases instead of confining his attention to diagnosis and treatment. A few points call for criticism. Dr Thomson is perhaps inclined to over-estimate the value of alcohol in the treatment of acute infections, and still regards this drug as a cardiac stimulant whereas the value it has seems to be confined to its narcotic action. The statement on page 143 that practically all are agreed that tracheotomy is superior to intubation⁴ should be qualified in view of the fact that in

many clinics on the Continent and in the United States intubation is the method of choice for relieving laryngeal obstruction and primary tracheotomy is rarely employed. We have noticed three important omissions. In the brief chapter on typhus fever there is no mention of the Weil-Felix reaction, which is now generally held by competent authorities to possess the same diagnostic significance in typhus as the Wassermann reaction in syphilis. In the discussion of the treatment of cerebro-spinal fever we do not find a description of intraventricular puncture, which has proved a valuable method for the removal of fluid and injection of serum when lumbar puncture has failed. Lastly, in the description of the differential diagnosis of enteric fever and lobar pneumonia no mention is made of blood examination.

The book, which is clearly written and essentially practical, will serve as an excellent introduction to the study of the commoner infectious diseases.

BIOLOGICAL THERAPY

Biological Therapy,⁴ a small volume prepared by Messrs Parke, Davis and Co for the use of the medical profession, contains summaries of the evidence regarding vaccine therapy, serum therapy, phylacogen therapy, gland therapy, and the diagnosis of protein sensitization, and also gives lists of the preparations manufactured by the firm. The first half of the book consists of a new and enlarged version of the firm's handbook on vaccine therapy, of which many editions have already appeared. It is written by Sir Almroth E. Wright and members of the staff of the inoculation department of St Mary's Hospital, London. This section may therefore be taken as giving an authoritative summary of the views of this school regarding the use of vaccines in disease. The subject is treated in a very clear manner. Great emphasis is laid on the fact that the problem of greatest importance and greatest difficulty in vaccine therapy is the discovery of the correct dose. The articles on serum therapy call for little comment, since the main facts in this field are well established, and only five pages are devoted to the more disputable question as to the therapeutic use of phylacogens.

The second half of the volume is occupied chiefly with gland therapy, a subject which is, of course, rather controversial and extremely difficult to treat briefly. The well established facts regarding the use of dried thyroid in cases of definite hypothyroidism are summarized, of the use of dried thyroid in other cases it is said:

"With the other conditions which have been more or less loosely associated with thyroid hyposecretion (thyroid insufficiency) the results as might be expected have been more or less irregular. Thyroid therapy is not to be regarded as a panacea for all of the ills which have been described in connexion with thyroid disturbances but its intelligent application will often prove of great benefit in some of the more or less obscure types of thyroid insufficiency."

This appears to be a very fair summary of our present state of knowledge on this subject. As regards parathyroid therapy it is stated:

"So many indications for the administration of parathyroid gland substance have been put forward that there is a danger of the remedy being regarded with scepticism and ignored even in those cases in which its exhibition has been followed by the most satisfactory results. In the following pages only those cases have been quoted that have been reported in the medical press or contributed by responsible authorities."

Following this we have seven pages summarizing the many and various diseases for which parathyroid therapy has been recommended. The writers however, must have exercised a considerable critical censorship to have kept the list within this limit. Accounts are given also of the actions of the following extracts: suprarenal, pituitary, ovarian, corpus luteum, mammary gland, thymus, and pineal. The note on the last named extract is a model of reserve.

The administration of pineal gland substance is to a great extent empirical and clinical evidence so far available is mainly suggestive. The gland substance however, is supplied with full assurance as to genuineness for physicians who may desire to use it though no claim is made with regard to any remedial virtues that it may possess.

⁴ *Biological Therapy including Vaccine Therapy Serum Therapy Phylacogen Therapy Gland Therapy Diagnostic Proteins* London Parke Davis and Co 1925 (Demy 8vo pp 198)

³ *The Diagnosis and Treatment of the Infectious Diseases* by Frederic H. Thomson M.B. C.M. DPH London H. K. Lewis and Co Ltd 1924 (Cr 8vo pp viii + 203 10 figures including 7 plates, 7 61 net)

The medical profession has for years been deluged with commercial literature booming glandular therapy in a most uncritical and unscrupulous manner. It is a pleasant change to find a commercial firm dealing with this subject with a sense of responsibility and restraint. We do not wish to suggest that all the claims made in the volume under review are certainly or even probably true, but in every case they can be supported by reputable evidence. It must be recognized that it is impossible to summarize the subject of glandular therapy in a manner that will meet with general acceptance, since the evidence available is both imperfect and contradictory. The summary under review, however, comprises very favourably as regards its caution and restraint with most of the literature on this subject.

The volume *Biological Therapy* is, we are informed, circulated exclusively amongst medical practitioners and is being offered free to all members of the profession who desire a copy.

NOTES ON BOOKS

SIR J. J. THOMSON, Master of Trinity College, Cambridge, delivered the first Lison memorial lecture at Guy's Hospital last May. It was on *The Structure of Light*, and is an attempt to provide a theory on light partly corpuscular and partly undulatory. The corpuscular theory began with Newton; it was discussed and supported by Laplace and Poisson, and had an undisputed sway until the end of the eighteenth century. Then came the English physician, Thomas Young, with the undulatory theory, the mathematical development of which was due to the Frenchman, Fresnel. It was almost universally accepted until quite recently. It was shaken up by the discovery of the X-rays. Planck revived something like the corpuscular theory and propounded his law of the quantum, which, again, has been very generally accepted. Sir J. J. Thomson summed the matter up by saying that the position is that all the optical effects point to the undulatory theory and all the electrical to something like the corpuscular theory. Taking up Maxwell's electro-magnetic theory of light, Sir J. J. Thomson elaborates another in which the corpuscular, or quantum, idea is combined with the undulatory. It will no doubt, receive at the hands of physicists the full consideration it deserves. The lecture was founded in memory of Mr. Alfred Henry Lison. For twenty years he was a staff lecturer in physics for the Oxford University Extension Delegacy, and all through his life he was a most successful public lecturer; from 1912 he held the office of secretary to the Gilest Educational Trust. In 1906 he was appointed lecturer in physics at Guy's Hospital, and it was while examining a wireless aerial on the roof of the medical school that he slipped and crashed through a skylight, receiving internal injuries which caused his death four days later (February 4th, 1923). The idea of establishing an annual lecture in his memory originated among his friends on the staff of Guy's Hospital and its medical school. It had the hearty support of the Gilest trustees and the response to a public appeal enabled the idea to take practical shape.

The *Catalogue of British Scientific and Technical Books*, published by the British Science Guild, is a volume that should be of great service to anybody who wants to know what books to buy for the study of any branch of science and technology. The first edition was published four years ago; the second, now before us, is dated May, 1925, and contains the titles of nearly ten thousand books under 51 sections and 555 subsections. There is a long list of addenda, a list of publishers, and an index to subjects and subject titles at the end of the volume. The book seems very complete and well up to date, and is admirably fitted for the use of the general inquirer and the orientation of specialists in the many departments of science and technology for which it caters.

The writing of a scientific paper always turns out to be more difficult than it seemed at the outset. Before pen and paper were collected the idea seemed clear as crystal, but faced with the blank and staring page its outline became less definite and its substance less transparent. Very quickly we become aware of the difficulties of composition. In such a mood, or better before it overtakes him, the author should, of course turn for guidance to the wisdom of the late Sir Clifford Allbutt in *Notes on the Composition of Scientific*

Papers. But besides the difficulties of composition there are others which spring up at a later stage when the thought is out on paper and the troubles of composition past. Now we are confronted with the technical difficulties of the headings of sections, the punctuation, the form of illustrations, tables, graphs, etc. the correct expression of citations and references. Help at this stage will be found in a useful little work, entitled *Preparation of Scientific and Technical Papers*, by S. I. MITTAS and J. S. YOUNG. This is a guide book to the correct expression and arrangement of a scientific communication. It contains a good deal of common sense advice about the orderly setting out of a subject and the use of clauses and correct grammar, but it is not for this that we wish to praise the book, for what the authors say on this score, though useful, is not distinctive. The chief merit of the book is that it is a handy little dictionary; it seems to answer all the irritating technical questions connected with the publication of scientific papers. For instance, the reader will find here information about corrections and alterations in the manuscript for the printer, the kinds of type the use of italics, the proper way to express the names of plants and animals, the signs employed in proof reading, and so on.

The Harvard Health Talks delivered at the Medical School of Harvard University provide in popular language information on medical subjects of general importance, and thus educate the public in the principles of hygiene. In the twelfth of these attractive little volumes Dr. CHARLES MACFARLANE, the university professor of psychiatry, speaks of *A Present-day Conception of Mental Disorders*, and asks his audience to consider the topic to be that of men, women, and children in difficulty suffering, hoping, thwarted, groping, and not to regard it with the vague feeling of mystery that the term 'mental disorder' may connote the word 'mental', indeed, is uncanny, and nervous is preferable. These disorders form a motley group, including respectable bankers peevish with their wives, scrupulous housewives with immaculate and uncomfortable homes, children with night terrors, earnest reformers, intellectuals, aesthetes and delicate invalids, evasive and tyrannical with manifold symptoms and transitory dramatic episodes. This charming lecture lays stress on the view that mental disorders can be explained in the light of the same general principles that explain the mechanism of the organs of the body, the evolution of the instincts, the origin of human culture, and the early phases of individual development in infancy and childhood.

Preparation of Scientific and Technical Papers. By Sam I. Mittas and Emma Saxena. Yale, Baltimore, Williams and Wilkins Company, London. Baillière Tindall and Cox, 1925. (Cf. 8vo pp. 113, 7s. 6d. net.)
* *A Present-day Conception of Mental Disorders*. By Charles Macfarlane. Cambridge, M.D. 1906, professor of psychiatry in Harvard University. Harvard Medical Talks 12. Cambridge, Mass.: Harvard University Press, London: H. K. Mulford Oxford University Press, 1924. (Fcap. 8vo pp. 54, 1 dollar.)

PREPARATIONS AND APPLIANCES

A Modified Mucus Catheter

Dr. BETHEL SOLOMONS, M.R.C.P. (gynaecologist to Mercer's Hospital, Dublin) has had made a mucus catheter on the same idea as the Record hypodermic syringe. It is shown in the illustration. Its advantages over the ordinary pattern are (1) that the mucus is made of glass so that the mucus can be seen and will not be sucked into the doctor's mouth (2) that it is easy to clean. It has been made to his instructions by Fanning and Co. Dublin and will be supplied in a box to prevent breakage in the bag.

A Slotted Bicycle Saddle

A bicycle saddle has been designed with a longitudinal median slot extending over its entire length; the width of the aperture is adjustable at both ends. It is claimed that this device obviates pressure upon the pubic region and is beneficial in cases of haemorrhoids or after operations for prostatic enlargement and anal fistula. We are informed that the saddle is made by The Leatheries, Ltd., Sampson Road North Birmingham.

An Insecticide Flit

An insecticide called Flit, produced by the Nupol Laboratories, New Jersey, U.S.A., is supplied by the Anglo-American Oil Company, Albert Street, Camden Town, N.W.1. It is used in a sprayer which is supplied with each outfit and is stated to destroy all insects such as flies, fleas, cockroaches, bed bugs, and their eggs. The price for a complete outfit is 5s. 3d. a 16 oz. can of fluid costs 3s., and the sprayer separately 2s. 3d.

* *The Structure of Light*. By Sir J. J. Thomson, O.M. The Frobenius Memorial Lecture, 1915. Cambridge: The University Press, 1915. (Imp. 16mo pp. vii + 38, 8 figures, 2s. 6d. net.)

† *Catalogue of British Scientific and Technical Books*. Second edition (entirely revised and enlarged). London: British Science Guild and A. and F. Dore, Ltd. 1925. (Dem. 8vo pp. vii + 489, 12s. 6d. net.)

THE STATE OF THE PUBLIC HEALTH

SIR GEORGE NEWMAN'S REPORT FOR 1924

[Concluding Notice*]

GENERAL EPIDEMIOLOGY

ENTERIC and paratyphoid fevers are not differentiated in notifications, but the total of both is 4,121 cases, against 3,211 in 1923 and 2,414 in 1922. The increase is regrettable, but it is pointed out that the decline has been exceptional in recent years. As regards paratyphoid, inquiry failed, in most outbreaks investigated, to elicit the means by which the disease had been spread. An account is given of various local epidemics, including that at Chorley in Lancashire, which was the subject of a special report by Dr. W. V. Shaw (BRITISH MEDICAL JOURNAL, March 21st, 1925, pp. 563 and 565). In an outbreak of enteric at Luton an itinerant ice-cream vendor seems to have been a carrier. In another, at Bethnal Green, in the last quarter of the year there were 65 primary cases with 12 deaths, and the infection was ultimately traced to milk, the manager of the dairy having been affected, not with influenza as at first supposed, but with enteric as diagnosed immediately after his removal to hospital. Scarlet fever is to be the subject of a special report in an early date.

Diphtheria and the Schick Test

The prevention of diphtheria is discussed in some detail in relation to the value of the Schick test. Two schools in the South of England are contrasted. In one, 220 children, mostly of rural origin, attending a school where there had been no diphtheria for years, were, naturally, highly susceptible when infection was introduced by means of a sickly child with "septic tonsillitis" which proved fatal. Of 122 older children, 83 (69 per cent) were found susceptible when tested, and 39 (31 per cent) immune, while of 63 younger children no less than 85.5 per cent were susceptible, and only 14.5 per cent immune. "Active immunization" was the method adopted for dealing with the outbreak, and "toxoid" antigen was employed in view of the great susceptibility of the children. The results were not so satisfactory as those usually obtained with "toxoid-antitoxin." In the other school there were between 400 and 500 boys, and 21 cases of diphtheria (one fatal) had occurred in less than a year, 20 of the children had been less than a year at school. The Schick test was carried out, and among 432 boys aged 6 to 15 years, 54, or 11.2 per cent, were found susceptible, and 378, or 88.8 per cent, immune. This school had mainly been recruited from urban districts, but even so the high percentage of immunity was remarkable. Reference is made to the account of the Schick test in Edinburgh given by Dr. Robertson (not Robinson, as in the report) before the Society of Medicine on the Royal Commission on the Prevention of Disease, and it seems ripe for consideration whether this method of protection more generally available. The co-operation of local education authorities would be necessary.

Influenza

Influenza is held to be in our own time like one of Sidenham's "epidemic constitutions." The recent type has, in most cases, been indistinguishable from a severe cold, but in some cases gastro-intestinal symptoms were common. The total number of deaths from influenza registered in England and Wales in 1924 was 13,986 as against 8,461 in 1923, and 21,498 in 1922. An account is given of outbreaks in two public schools.

Infectious Diseases of the Nervous System

Infectious diseases of the nervous system receive much attention in the report especially encephalitis lethargica, of which there were 5,039 notifications—much the highest figure since it became notifiable in 1919. The other

diseases of the group shew also some increase. All of them are believed to be conveyable by personal contact, and unrecognized errors may be suspected. It is remarked that the excessive humidity of the year "may possibly have had some bearing upon the enhanced morbidity of these few diseases." The heaviest incidence of encephalitis lethargica was in the second quarter of the year. Its urban and rural incidence, mortality, seasonal prevalence, predisposing causes, infectivity, after-effects, prevention, and treatment are discussed, and also its relation to influenza—an interesting question which is likewise dealt with by Sir William Hunter in his London County Council Report, noticed in our issue of August 9th, 1924 (p. 247), and also with some fullness in his Report for 1924 quite recently issued.

Tuberculosis

Unfortunately it cannot be said that within the past five years there is any appreciable decline either in prevalence or mortality of tuberculosis. Of pulmonary cases the tables show that 57,844 became known in 1920, and 55,040 in 1924, but non-pulmonary cases, which were 15,488 in 1920, were 17,684 in 1924, so that in the total there is very little change, and indeed 1924 has had more cases than either of the three immediately preceding years. In mortality also there has been little alteration within the lustrium. In 1924 the deaths from pulmonary tuberculosis numbered 32,690, against 32,097 in 1923, but in other forms there was a slight diminution—from 8,691 to 8,413—and if 1920 be compared with 1924 a trifling decline appears, from 32,791 to 32,680, while in other forms of the disease there is a very appreciable fall—from 9,754 to 8,413 deaths. None of these figures are rates per population, which has, of course, somewhat increased, and an appendix table gives the standardized death rate per million from the pulmonary disease as 843 per million in 1920 and 801 in 1924. But the statistics for the five years are not satisfactory, and it is suggested in the report that the conditions associated with lack of employment supply the probable explanation.

Notification, however, presents another aspect. An increase of 1,500 in pulmonary notifications in 1924, as compared with 1923, and a trifling increase in non-pulmonary may be partly due to more complete compliance by medical practitioners with the Regulations issued in August, 1923. Yet there emerges the very regrettable fact that no fewer than 8,434 cases became known to medical officers of health, not from formal notification, but from death returns, etc. It is pointed out that there may be delay in the patient consulting his doctor, delay in diagnosis, and failure to comply with regulations. But these considerations are no sufficient justification for the omissions, and Sir George Newman remarks that the solution must be sought in the education of public opinion. Even medical officers of health cannot be excused. The importance of this matter is such that we quote in full the following paragraphs from the report.

Evidence from various sources suggested that in a number of urban and rural areas the Medical Officers of Health were seriously irregular and negligent with regard to the register of notifications of tuberculosis required to be kept by the Tuberculosis Regulations of 1912 and that they had failed to revise their registers periodically as required by Article 4 of the Tuberculosis Regulations of 1921. Apparently the Medical Officers of Health of many smaller urban and rural districts have taken the view that they need not interest themselves particularly in tuberculosis, since the responsibility for carrying out the official scheme of treatment of this disease was vested in the County Council and not in the Local Sanitary Authority.

Tuberculosis is a disease of so much importance in connection with the public health problems of an area that it seems particularly unfortunate that any Medical Officers of Health should assume that the special position of the County Council in relation to schemes of treatment in any way detracts from the responsibility of the District Council in regard to this disease. The Tuberculosis Regulations of 1912 specifically indicated the duties and powers of Local Sanitary Authorities in connection with tuberculosis and it is essential that these duties and powers should be exercised. Where County Councils and Local Sanitary Authorities have collateral powers it is indispensable that the work should be carried on in close co-operation arrangements being made to prevent overlapping.

It was found that in some areas the tuberculosis notification register was either non-existent or had not been revised and kept up to date so that the Medical Officer of Health was unaware as

to the number of notified cases of tuberculosis in his area. It was consequently considered necessary to take steps to ensure that due attention should be paid to the question of the proper and periodical revision of the tuberculosis register. The Public Health (Tuberculosis) Regulations 1924 dated 18th December 1924 (Statutory Rules and Orders, 1924 No 1411) have therefore been issued.

The steady diminution since 1917 in the mortality from non-pulmonary tuberculosis is a redeeming feature, and is attributed partly to a safer milk supply, partly to institutional isolation of advanced cases of pulmonary tuberculosis, and partly to extended facilities for residential treatment of non-pulmonary cases, with excellent results even in severe bone and joint conditions. Indeed, the care of the advanced case, whether pulmonary or not, is an important influence in limiting spread of infection in families, and it is very desirable that small units of hospital accommodation should be available within easy reach of the homes of patients, though such units should be so administered as not to acquire the reputation of being merely homes for the dying.

Regarding the subject of results of sanatorium treatment, reference is made to the report issued by the Medical Research Council in July, 1924, as to patients treated at Emsayn Sanatorium. Notwithstanding disappointed hopes, it is held that sanatorium treatment "offers a more solid prospect of general all-round gain to the community in the combat against this disease," and that "at present there is no alternative." The points to be attended to in early notification, sufficient period of residence, sound principles properly applied, and after-care assistance. Cure and after-care, occupational training, and methods of treatment, including vaccine therapy, are all discussed in this valuable section of the report, but space forbids their further exposition here.

ATMOSPHERIC POLLUTION

THE pollution of the ocean of the atmosphere in which we are all immersed may be regarded as one of those evils called necessary which are inseparable from civilization in temperate latitudes. Dust is universal in the city and even in the country. Smoke is being continually discharged into the atmosphere and every day the ever increasing volume of heavy traffic is grinding down wood, stone and metal into impalpable particles to be blown about by every breeze. All this is quite apart from the myriads of minute living things—yeasts, other fungi, bacteria, spores, etc.—which contribute their substance to the omnipresent dust.

In 1912 a Smoke Abatement Exhibition was held in London, and one of the things accomplished by the delegates of the municipal authorities present was the establishment of a committee for the investigation of atmospheric pollution. This committee has now issued its tenth report.* It covers the work of the year ending March, 1924, the twelfth year of activity. The committee consists of members appointed by the Meteorological Office, by the Department of Scientific and Industrial Research, and by a technical subcommittee of experts, representing chemistry, physics, engineering, and other applied sciences. Sir Napier Shaw, F.R.S., is chairman.

The method of measuring the aerial pollution by means of the "standard gauge" has been fully described in previous reports. In the year under review forty-five gauges were in operation. Besides reporting upon the total deposit of impurities, the committee was able to estimate all of the following materials which contribute to the pollution of the atmosphere—namely, soluble ash, ash soluble on ignition, tar, carbonaceous matter, sulphates, chlorine and ammonia. Saturdays and Sundays for obvious reasons, are studied in a group by themselves, the other days being called "week-days."

All days for the purposes of this study are divided into two types: ordinary days and "7" days the latter being those on which the smoke haze was at some hour very thick.

A "7" day is defined as one during any portion of which the maximum impurity is equal to or greater than 1.28 milligrams of dirt per cubic metre of air. Three types of instrument have been used: (1) the standard deposit gauge, the purpose of which is to collect the deposited impurity at any station so as to compare the amounts which fall in different localities; (2) the automatic filter, which hourly measures the amount of suspended impurity; and (3) the jet dust counter, which allows of a microscopic examination and enumeration of the dust particles. A new form of instrument is described, the settlement dust counter, designed by Dr J. S. Owens, the consulting engineer. It measures the amount of dust or bacteria in the air even when the dust particles are very coarse, such as are found in warehouses for grain and in similar buildings. The ordinary method of exposing a plate has little value as a quantitative method, for the deposit on such a plate varies as the size of the particles, their density, the temperature of the air, and the degree of its turbulence. Further, the deposit is made from an unknown volume of air.

The figures for the total deposits are striking. Expressed in metric tons to a hundred square kilometres of surface in a year (omitting hundreds) we have for London from 8,000 to 16,000, for Glasgow from 9,000 to 12,000, for Central Birmingham 17,000, for Blackburn 8,000, for Leeds from 15,000 to 16,000, for Newcastle-upon-Tyne 34,000, for St. Helens 15,000, for Liverpool from 23,000 to 25,000. At Blackburn in winter there were 47 per cent ordinary days and 53 per cent "7" days. In summer in Blackburn on a week-day the deposit of impurity begins about 4 a.m., rising to a maximum at 7 a.m., whereas on Sundays the maximum is not reached until 10 a.m. This is taken to mean that the inhabitants, by remaining longer in bed on Sundays, prolong by three hours the period of natural salubrity.

The ratio of total smoke on Sundays to week-days in that town is as 2,000 to 3,677. Assuming that the Sunday smoke is exclusively domestic, while the week-day is domestic plus factory, the ratio of factory to domestic smoke is as 1 to 1.85. The instruments of precision have permitted a high degree of accuracy being attained in the work.

In previous years it had been found that 10,000 particles went to a milligram; the observations now reported confirm this, about 10,000 particles per cubic centimetre corresponding to 0.8 milligram per cubic metre.

Research is being conducted into the ability of light to penetrate haze or fog—a subject of great practical consequence. As might have been expected, the greater the number of particles suspended, the greater is the percentage of light thereby obstructed. The contrast photometer is used to measure the amount of light transmitted through a known distance of hazy atmosphere. In round numbers there is a loss of 50 per cent of light in traversing 50 feet of air when there are present 32,000 particles per c.c.—that is, by 2.6 milligrams per cubic metre. As we ascend from the ground the number and size of the particles diminish, as has been ascertained through observations by balloons.

The average diameter of particles collected at the surface was about four times that of those at 10,000 feet, so that the ratio of the total weight of particles at the surface of the ground to that of those at 10,000 feet was 530 to 1.

The spectroscopic appearance of dust volatilized in the electric arc has been studied, but as yet few reliable data have been collected.

The abnormal darkness of January 23rd, 1924, has been the subject of extensive investigation. The "Load diagram" for the power station in the City Road shows that at 2.30 p.m. on that day this station had to send out between 13,000 and 14,000 kilowatts the normal output for the same time of day at that time of year being 10,000 kilowatts. At the height of the observation no lights were visible beyond 500 feet; the impurity was equal to a precipitation of between 1 and 2 milligrams per cubic metre.

British Medical Journal.

SATURDAY, AUGUST 8TH, 1925

A PURE MILK SYMPOSIUM

THE experiment, suggested a few years ago by Dr. Fothergill, of a Section of Medical Sociology at the Annual Meeting of the Association, has been amply justified by its results. In the discussion on pure milk this year at Bath (of which a full report appears at p. 241) a high level of interest was maintained. There were present representatives of county councils, medical officers of health, and sanitary inspectors, of veterinary surgeons, farmers and milk purveyors, and of eleven milk societies. In fact the only interests not directly represented in this discussion on pure milk—a matter brought to the notice of the public originally by the doctors—were those of the ordinary consumer and the retailer. The interest of these comprehensive sections of the community may be summed up perhaps in a demand for efficiency with economy, and it is in the light of such a demand that the discussion should be studied.

The discussion fell into two parts in the morning and in the afternoon with the standard of purity of milk, taken to obtain pure milk, and its cost. It will be useful in the first place to attempt to define the terms used in the discussion. Pure milk presumably is milk which has not been tampered with, which has not been diluted with water, which has no added preservatives, and which is clean. The meaning of clean milk is fairly definite. It is based on the bacterial count, and is related especially to the presence and numbers of coliform bacilli. The difficulties in producing completely clean milk are so great that the cost of the milk would be prohibitive. It has been thought well in order to stimulate the production of milk that is as clean as circumstances will allow, to introduce a system of grades. (1) Certified milk is obtained from cows tuberculin tested and inspected by a veterinary surgeon every three months. The number of bacteria must not exceed 30,000 per c.c.m., and must not contain *B. coli* in 1/10 c.c.m. on delivery. (2) Grade A milk must appear on each cap of the milk the date of production and the words "Certified milk" except that the maximum bacterial count must not exceed 200,000 *Bacillus coli* and the name of the farm. The cap must be stamped with the address of the licensed bottling establishment. (3) Grade A milk is from cows that need not be tuberculin tested but the herd must be inspected every three months by a veterinary surgeon. The bacterial count allowed is as in (2). The milk must be distributed from the farm in unventilated sealed containers, dated, and stamped. (4) Grade A milk which after pasteurization does not contain more than 30,000 bacteria per c.c.m. and contains no coliform bacilli in 1/10 c.c.m. (5) Pasteurized milk is milk that after pasteurization does not contain more than 100,000 bacteria per c.c.m. It need not be bottled. To these Dr. Chalmers

Watson wished to add a sixth grade—milk only suitable for use when cooked (BRITISH MEDICAL JOURNAL May 16th, 1925, p. 943). From this summary of the authorized grades of milk it will be seen that the term 'Grade A' is misleading, and that milk to which this title is given is really Grade C. One of the speakers in the discussion at Bath commented strongly on this deceptive nomenclature.

From the addresses read before the Section it is plain that the matter under discussion involved two main problems. First, the production of milk as clean as circumstances will allow, secondly, the production of tubercle free milk. The subject matter of these problems was debated under two headings: the standard of purity of milk and the means and cost of obtaining pure milk. Some of the speakers asserted once more that it was impossible under all conditions to maintain the standard of 3 per cent butter fat and 8.5 per cent solids not fat though difficulties with individual cows are often neutralized by the mixing of milk in bulk. Enlightenment was asked for as to any feasible way of increasing the vitamin content by feeding methods. With regard to pasteurization doubt was expressed as to the ability of very poor parents to pay for fruit juices to replace destroyed vitamins and Dr. Ene Fritchard gave the interesting information that he had been quite unable to find any evidence in literature or in his practice of harm from the ingestion of toxins of either pythogenic or non pythogenic organisms.

An important part of the discussion was concerned with bacterial questions—the production of clean milk, with, on the one hand, a minimum number of bacteria (especially *Bacillus coli*), and on the other an absence of the tubercle bacillus. Putting aside for the moment all question of tubercle, and dealing only with dirtiness as evidenced especially by the coliform bacillus, there appeared to be no doubt from the discussion that it is not difficult to produce milk that will reach the standard of Certified or of Grade A. Professor Walker Hill went so far as to say that instead of a bacterial count of 200,000 a count of 200 was possible even in summer and several speakers asserted that they produced milk with a count of less than 1,000. At the same time it is certain that the general production of Grade A milk is not practicable without a vast amount of further education. The general production of Grade A milk requires the greatest possible cleanliness in the collection of the milk. The cowsheds, if reasonably clean are of far less importance than the cleanliness of the workers of the pails and of the cows. Anyone who is old enough to have observed the struggles of the surgeons who were pioneers in aseptic surgery and their difficulties in keeping their hands out of their pockets or off their spectacles, will sympathize with the less educated milker in his attempts at keeping primitive methods with the farmer in the constant supervision he has to maintain and especially with the small farmer who has to expend money on the provision of suitable plant and time on the instruction of his workers in its use and its maintenance in cleanliness and good order. The production of certified milk with the obligation of bottling on the farm in such a way that when delivered to the customer it shall contain a minimal number of bacteria, is at present, quite beyond the capacity of anyone except the owner of a crack herd. The attitude most suitable for the present state of education and for present conditions is probably, as follows. Let the general production of Grade A milk (unpasteurized) be the ideal

aimed at, develop education as to the value of clean milk amongst producers, distributors, and consumers, but pasteurize is the safest course until education is more advanced. The objection that a general resort to pasteurization may delay progress in getting really clean milk is not valid, inasmuch as when he has something of value to offer to the public if not too much harassed by Government control, does not long allow himself to be quiescent. Attempts to go too fast are apt to produce again such statements as that made in one of the addresses: 'Recently five cases of bovine tuberculosis occurred in infants fed entirely on Grade A milk from a most reputable dairy.'

Turning now to the question of tubercle the discussion showed that a far more difficult problem was presented. In the face of these difficulties, and in order that the public may not lose its head (though it is perhaps unlikely to do so, having had the subject before it so long and so continuously) it might have been well if the opening of the discussion had begun by stating the magnitude of the problem. How much disease is caused by bovine tuberculosis? One of the speakers said that between five and ten thousand children die annually from tuberculosis, chiefly abdominal, and for that reason perhaps mostly bovine. Therefore, though the mortality is not enormously high yet, as was observed, much suffering and crippling is caused in many other non-fatal cases. Most of us do not desire to run the risk in ourselves or in our children of suffering from bovine tuberculosis, although there are some who think that tuberculous milk may serve to immunize children against tuberculosis. The matter is not yet ripe for dogmatic statement, there has been a very great decrease in mortality from tuberculosis, and panic measures are not justified. It will be possible to examine coolly the remedies proposed, and to refrain from expensive procedure unless the evidence that it is necessary is well established. It appears that there are about 2,500,000 milking cows in this country. It appears, also, that about 1,000,000 of these are tuberculous or would react to the tuberculin test. In addition, of course, there are large numbers of non-milking animals affected by the disease. It is impossible to eliminate bovine tuberculosis at once. As one of the speakers pointed out the result of an attempt to do so would be a milk famine. The Government has recently introduced an Order similar to the Tuberculosis Order of 1914 to come into force on September 1st next, when the Milk and Dairies Acts take effect. These Acts prohibit the use for the production of milk of any cow which is giving tuberculous milk, or is suffering from tuberculosis of the udder or tuberculous emaciation. The Order will compel the slaughter of all such cows and any other bovine animal which may be suffering from tuberculous emaciation or from a chronic cough and showing definite clinical signs of the disease. The owner is required to report such an animal to the police, and veterinary surgeons are required to report such animals to the local authority. After full veterinary inquiry such animals will be slaughtered, and the owner will be compensated at the rate of three quarters of the market value in non-advanced cases and one quarter if the animal is affected in an advanced form. The minimum payment is 45s. This Order raises many questions, some of which are left in doubt by the discussion at Bath. The tuberculin test appears to be reliable but some difference of opinion was shown to exist as to the respective value of the subcutaneous and the intradermal methods. The test is somewhat exacting, it requires

the taking of the temperature at intervals for eighteen hours. It does not seem certain how often it should be repeated and it appears to be not easy to maintain a tubercle free herd free from reinfection. The Order is confined to grosser lesions which can be recognized without the tuberculin test. But is it certain that a cow gives no tuberculous milk until the lesions are sufficiently gross to attract the attention of the farmer, the veterinary surgeon or the inspector? During the discussion in the House of Commons, reported in the JOURNAL of July 25th (p. 179) it was stated that the cost of compensation would probably be about £67,000 a year and that only £17,000 of this would fall upon the local authority. But has any calculation been made of the increased inspection that will be required and of the fees for veterinary services included? Mr. Quinlan Chairman of the Sanitary Inspectors' Association asserted that inspection was effective in the Liverpool district. But Mr. Maggs was equally strong in asserting that in many places inspection is a failure. If he is right a more thorough system of control will have to be added to the cost of the Order in such districts. As to tuberculous meat, it would seem that the lesions in the animals condemned will be too gross in most cases to allow of the carcasses being sent to the butcher but is disease of the udder always associated with such serious internal lesions as to need condemnation of the carcass for meat purposes?

The questions as to the stage of the disease at which a cow begins to give tuberculous milk, and as to the necessity for the tuberculin test to all milking cows, and the difficulties in the way of applying it, suggest that the results will be more satisfactory if hasty action is avoided. Dr. Stenhouse Williams in his opening remarks at Bath, said that bacteriological standards could be employed in two ways—either as a method of public health control, or as a means by which the true essentials of the methods of handling milk, and the need for them if the trade is to be in a healthy state can be brought home to the industry. And he added: 'The latter function will, in the end, to a great extent eliminate the necessity for the former.' The same remark can be applied to the problem of tuberculosis. The lines of progress in eliminating tubercle may be administrative or educative. The administrative method involves inspection, veterinary investigation, condemnation of unfit cattle, destruction and compensation. At the present time sufficient machinery does not exist in most rural and many urban areas to make this method effective. Administrative control will have to be made general, and, however moderate the cost of compensation, it seems probable that the cost of administration must be great. Moreover, control is apt to arouse opposition and unless in the present case its application is very gentle and judicious there will be many attempts at evasion. One of the speakers at Bath said that he had little doubt that the minimum compensation of 45s. will tend also to be the maximum. The educative method proceeds on different lines, involves less expenditure is less irritating but is possibly slower in its action. Dr. Savage, M.O.H. for Somerset, was cheered when he gave his own solution of the difficulty of milk control—namely, to give the owner of the milk prompt notice (without prejudice) of the fact that his milk was below standard, and to provide facilities for examination before any question of prosecution was entertained. It was noticeable also that the value of milk competitions was mentioned by a large proportion of the speakers and disputed by

none. Educative measures include the promotion of milk competitions, as is being done by many large firms of dairymen, instruction of the public as to what it should ask for, advisory assistance by administrators, exhibitions of good methods at agricultural shows, and, as a last resort only, the prosecution of those who offend through design and not through ignorance. The money that would be spent on the enforcement of harsh regulations would be more than sufficient for extensive propaganda.

The present position of the supply of pure milk is one in which the immemorial contest is going on between State control and voluntary effort. If every human being aimed at the ideal there would be no need for control. If everyone was controlled the human being would become a machine, and progress would stop. If these premises are accepted, then the aim should be a minimum of interference consistent with a reasonable probability that matters will improve. The symposium at Bath showed that the question is in the hands of very capable men, that the milk supply has improved enormously in purity, and is improving every day, that further examination and experiment will continue, and that the safest plan to avoid a setback to progress is that no rash step should be taken.

THE HEALTH GOVERNMENT OF ENGLAND

IN a discussion following a recent valuable and comprehensive address by Dr Andrew Balfour at the Royal Society of Arts one speaker remarked that a special merit of what they had listened to was that it left those who followed Dr Balfour absolutely free to start talking about any subject they pleased. The same comment applies to Sir George Newman's Report on the State of the Public Health in England in 1924, of which a concluding notice appears elsewhere in this issue. He surveys the world of hygiene from China to Peru, and the questions on which he comments are varied and important. We propose to confine ourselves to one subject which must at the present time be pressing itself on the attention of those who are most intimately occupied with questions of local government. In our issue of March 21st, 1925 (p. 565), we dealt with the subject of local government in rural districts, the article being called forth by a report by Dr W. V. Shaw, of the Ministry of Health, on a milk borne outbreak of paratyphoid fever in a Lancashire borough, due to the failure to take proper action of those responsible for the public health administration of the rural district from which the milk was supplied. The lesson which we drew from the deplorable occurrence was that it disclosed defects in the whole system of health government by the smaller sanitary authorities of England. The outstanding flaw is due to the insufficiency both as to population and valuation, of many of the areas in question—in insufficiency for which the power of local combination of adjoining areas for appointment of a medical officer of health is not always an adequate remedy. As a corollary we urged that the matter should receive the fullest consideration by Lord Onslow's Royal Commission on Local Government which, doubtless, is now engaged in the preparation of its report.

Sir George Newman's new survey of the health of England and Wales impresses on us afresh the fundamental importance of this question in its bearing on the future of sanitary government outside the great cities and the county boroughs. We do not revert to

the subject because the death rate and the infant mortality rate of 1924 have been higher than in 1923—annual fluctuations will occur in the course even of the steadiest improvement, nor because small pox, while mild in type, is becoming more prevalent year by year, though here the remarkable success achieved by the great and crowded cities in wading off the disease, as compared with what has occurred in certain lesser areas, is a fact of much significance. Enteric and paratyphoid fever, too, have increased within the past three years, but the same reservation applies to them notwithstanding the revelations of mismanagement in at least one rural district. The particular matter to which we wish most of all to call attention relates to tuberculosis. The steady decline in the prevalence of and mortality from pulmonary tuberculosis has practically ceased during the last five years. No doubt, in accounting for this, Sir George Newman is right in attaching importance to conditions associated with lack of employment throughout the country. But his report shows that there is more than this. Notification is the basis of measures for prevention and control. Yet in the year 1924 no fewer than 8,434 new cases of tuberculosis which had never been notified became known to medical officers of health, death returns being an important source of information. Causes of deferred notification mentioned in the report are delay in consulting a doctor, delay in diagnosis, and failure to comply with official regulations. These, each in its own measure, are relevant, but whether taken together or singly do not account for death registration being in a considerable number of cases the first intimation officially received of the existence of the disease. Making every allowance for difficulties, we are almost driven to the conclusion that medical practitioners are sometimes at fault in this matter. Obviously it lies with the medical officer of health insistently to invite the attention of the practitioners in his district to the necessity for notification as promptly as circumstances may render practicable in every case. But *quis custodiet ipsos custodes?* What if the medical officer is failing in his own duty? That question arises from a paragraph in Sir George Newman's report (p. 91), which is quoted in full in this issue at page 261, and suggests irregularity in keeping the registers of tuberculosis notifications. This, on the face of it, constitutes a very grave indictment of officers of "a number of urban and rural areas." The allegation should be read along with what he wrote in his preface to Dr Shaw's report on the outbreak of paratyphoid fever already mentioned. He there emphasized the necessity for constant vigilance on the part of the officers of sanitary authorities when dealing with even an isolated case of infectious disease, and the importance of prompt and continuous attention to cases among persons engaged in occupations associated with the production and distribution of food.

But, as insisted in our comments on that report, so in the present connexion, the entire blame is not to be laid at the door of the health officers. There are, to a great extent the victims of a system of local government which the country has outgrown. Many of them perhaps most of them have no diploma in public health. Many of them, perhaps most of them, whether with or without such diploma, are engaged in general medical practice, with all its worries and anxieties in respect of medicine, surgery, and midwifery. It is particularly difficult for them to maintain a proper official relation to their colleagues and competitors in practice, whose performance of

POST GRADUATE EDUCATION

then obligations under the notification and other Acts it is the health officer's duty to supervise. Further, it is not really practicable for an ordinary man to keep up, in the interests of his patients, his acquaintance with current advances in the science and art of medicine at the same time that he is responsible for knowing and obeying all the regulations, old and new, issued from the Ministry at Whitehall—such as the Tuberculosis Regulations of 1912, the Tuberculosis Regulations of 1921, and the Public Health (Tuberculosis) Regulations, 1924 (Statutory Rules and Orders, 1924, No 1411). Yet these regulations and many more are necessary in the public interest, and an immense task is thus reached in the health administration of many small urban and rural districts. As already urged, these districts are often too small that can neither pay for the whole time of a fully qualified officer, nor would they provide him a sufficient field in which to employ his energies or increase his experience. Attempts to meet the situation in that way would be both financially extravagant and administratively unsound. Rural and urban district authorities in charge of a population of only a few thousands—in some cases, indeed, of only a few hundreds—each district being theoretically responsible for the routine administration of the many Acts relating to public health, are preposterously unfit for the functions assigned to them in this respect. In the old days, when public health administration was now understood as undeveloped, and when very few medical men possessed a diploma in public health, such a system was better than none, and much genuinely good work was done. But, notwithstanding all that may be said in praise of the whole-hearted efforts of many men to fulfil the double duty of public and private work, the system has outlived its usefulness and should be scrapped. Districts requiring the whole time services of properly trained and qualified officers should be created in their stead, only such officers should be appointed, and the scale of salaries and the conditions of service should be such as to attract the right kind of applicants.

Sir George Newman's report provides the occasion for returning to this subject and at the same time emphasizes not directly, but by means of a plain statement of correlated facts, the urgency of the problem, and the need for taking the opportunity which the Royal Commission will afford of insisting on a fundamental change in the scheme of local health government throughout the counties of England.

NEW DEPARTMENTAL COMMITTEE ON
POST-GRADUATE EDUCATION

THE Minister of Health has appointed a Committee, of which he will be chairman, to draw up a practicable scheme of post graduate medical education centred in London. The Ministry will be represented on the Committee by Sir Arthur Robinson, K.C.B., First Secretary of the Ministry of Health, and Sir George Newman, K.C.B., M.D., Chief Medical Officer of the Ministry and of the Board of Education. The other members of the Committee are Lord Dawson of Penn, Sir Humphry Rolleston, Bt, Regius Professor of Physic, Cambridge, and President of the Royal College of Physicians of London, Sir John Blund Sutton, Bt, President of the Royal College of Surgeons of England, Sir Thomas Horder, Bt, M.D., physician to St Bartholomew's Hospital, Sir George Blacker, M.D., Dean of University College Hospital,

Medical School, Dr R. A. Bolam, Chairman of Council, British Medical Association (Newcastle on Tyne), Dr H. G. Dain, Chairman of the Insurance Acts Committee, Mr Herbert J. Paterson, F.R.C.S., honorary secretary, Fellowship of Medicine, Dr J. Parkinson, physician in charge, cardiological department, London Hospital, Mr H. L. Lason, ophthalmic surgeon, Guy's Hospital, Professor Hugh Macleod, M.D., St Thomas's Hospital, and Mr A. E. Webb Johnson, Dean of the Middlesex Hospital Medical School.

The appointment of this Committee is a result after a rather long interval, of the report of the departmental committee which in 1921 was instructed to "investigate the needs of medical practitioners and other graduates for further education in medicine in London, and to submit proposals for a practicable scheme for meeting them." It was presided over by the Lord of Athlone, then chairman of the Middlesex Hospital, and after a thorough examination of the position recommended that two post graduate colleges should be set up in London—one medical college and a college of hygiene.

The second recommendation was quickly realized. The Rockefeller Foundation munificently gave a capital sum of £400,000 for the erection of buildings for a College of Hygiene and Tropical Medicine, to serve not only the British Empire, but in some way also as an international centre of research and instruction. Parliament, at the instance of Sir Alfred Mond, then Minister of Health, voted £15,000 a year for maintenance. The College was constituted with the adhesion of the London School of Tropical Medicine, and that ship, if not yet afloat, is well advanced on the stocks.

The keel of the other has not yet been laid down. The Athlone Committee took a good deal of evidence and received written information from the British Medical Association, the medical schools, and other medical educational institutions in London, and also from the universities in England, from the University of Wales, and from the Universities of Edinburgh and Glasgow. The committee recommended that a school attached to a hospital centrally situated in London should be devoted solely to post graduate medical education, and that it should be a school of the University of London receiving substantial financial assistance from the Treasury through the University Grants Committee. It recommended also that a central office should be established to co-ordinate and develop the work of post graduate education in London, and that in the administrative building should be provided not only offices, but the accommodation necessary for social purposes. The committee advised further that in addition to the courses at the central school for the full time instruction of general practitioners, and at the existing post graduate colleges and schools, further facilities for post graduate study should be made available at non-teaching hospitals, and in Poor Law infirmaries, and that a large number of residential appointments and clinical assistantships should be created in hospitals and Poor Law infirmaries. The new Committee will doubtless take into consideration the work that is being done by the Fellowship of Medicine and also by the West London Post Graduate College and at the North East London Post Graduate College at Tottenham. It will also have the advantage of the advice of the British Medical Association, the Council having recently appointed a Committee on Post Graduate Education. Some curiosity may be excited by the fact that the

scheme of the new Committee is to be centred in London, but it is to be remembered that in many other centres post graduate medical education is a matter to which the university itself gives attention. This is true of Bristol, Birmingham, Manchester, Edinburgh, and Glasgow, and in a modified form at Leeds and Newcastle. Oxford and Cambridge also have classes which are in relation with the universities.

We understand that the members of the Committee met the Minister of Health last week, and that the first actual meeting of the Committee will probably be held early in October.

THE BRITISH OPTICAL INDUSTRY

BEFORE the war the British optical industry was thought in many quarters to be in a sadly unenterprising condition. This was not altogether true, for even then British optical manufacturers were producing the very best instruments in several fields of optical application, even if they were outwitted by foreign competitors in others. Since the war, in spite of financial and commercial disabilities, the original grinds have been consolidated, and conquests have been made in fresh territory. The history of recent progress was reviewed by Mr. Frank Twyman in his presidential address at the annual meeting of the British Optical Manufacturers Association. Mr. Twyman referred in particular to the construction of microscopes, where improvements had been made able in the illuminator, the objective, and the stand which holds the optical parts and the objective in their proper relative positions. With regard to the first of these elements, a dull ground illuminator has been developed which permits the use of higher powers than heretofore. A series of apochromatic objectives has been worked out, superior to any forthcoming from a foreign country, and, finally, the accuracy of focusing and the rigidity demanded by the recent work on filterable viruses has been met by the development of a special microscope stand, also of British design. In this connexion Mr. Twyman pointed out how essential to medical research is an efficient optical industry. A year or two ago instruments adequate to the investigation of filter-passing microorganisms were not in existence, but the investigators laid their requirements before the instrument makers, and within a period of months the instruments were forthcoming which enabled the research to be carried through. Mr. Twyman went on to describe the marked improvement made in British camera lenses, including those used for aerial surveying, for telephotography, for cinematograph work, and for process reproduction. Again, at the astronomical observatories it is British lenses which hold the field. The discs of glass for the largest telescope in the world have lately been successfully made in a British lens factory, this telescope, which will shortly be completed, is to be of 41-inch aperture, or one inch larger than that at the Lick observatory. Mr. Twyman thought it probable that most of the physical research now going forward in the world is being carried out with British-made instruments. Some very important apparatus had been made in this country for Japanese, American, and European universities, including even schools at Charlottenburg and elsewhere in the country of Abbe, the genius of Jena. Progress in optical instrumentation has, of course, depended on the supplies of optical glass and here also improvement can be recorded. Before the war there were but three makers of optical glass—one in Great Britain, one in France, and one in Germany. The British maker, although his glass was of excellent quality, listed only twenty-six varieties, which was insufficient for modern optics. That same maker now listed eighty optical glasses,

and two other British makers of optical glass have since come into the field. The Scientific Instrument Purchasing Association had done valuable work for the industry. Until recently the character of the abrasives used in grinding glass had remained unaltered since the early Egyptian dynasties, now, through the work of Sir Herbert Jackson and the Research Association—work of which full details cannot yet be given—an abrasive is forthcoming, of better quality and not dependent on foreign supplies. The Research Association has dealt also with the important question of the durability of glass and the stabilization of glass surfaces so that they will not become tarnished or cloudy. The colour of glass is now better understood, and the associated problem of producing a colourless glass has been successfully tackled. Work of a fundamental character on the theory of lenses, again, has been done at the National Physical Laboratory. Altogether the British optical industry is active in invention and development and in scientific research, and eager to prove its vitality.

A HEALTH DEPARTMENT FOR THE COLONIAL OFFICE

THE Committee of Supply on the Colonial Office vote Mr. Amery (Secretary of State for the Colonies), in the course of his speech on July 27th, made reference to the immense importance of the development of research into tropical diseases. It was, he said, one of the matters which would engage the attention of the new Committee on Civil Research (see *BRITISH MEDICAL JOURNAL*, July 11th, p. 76). It would investigate the problem of how to deal with the tsetse fly in Africa, and it was hoped that the temporary scheme of investigation to be carried out during the next year under the League of Nations would be followed by a much more comprehensive and effective campaign in subsequent years. He was inclined to agree that the increasing diversity of the work done in the colonies called for corresponding diversity in the central organization in this country, more extensive than the old method of dealing with all problems, including agriculture, medicine, and education by civil servants responsible for every aspect of life in a particular group or area of a colony. As a step in this direction he had decided to establish in the Colonial Office a chief medical officer and at least the beginnings of a health department, to enable the office to keep in closer touch with the health and research work which is being done, and to give more direct guidance and assistance to the medical officers who are working, often in great difficulties, especially in the tropical colonies. The step Mr. Amery has now taken is overdue. The late Sir Patrick Manson was for some years medical adviser to the Colonial Secretary on tropical matters, but his position was not well defined, and so far as we are aware he had no staff. Sir John Ross Bradford is at present Senior Medical Adviser to the Colonial Office.

THE EARLY TRAINING OF MENTAL DEFECTIVES

A COUPLE of years ago (July 21st, 1923) we commented favourably on a little book by Dr. John Thomson, entitled *Opening Doors*, which was written for the guidance of mothers with defective children. The same author has now written a short paper for nurses on "Mentally defective babies: their recognition, treatment, and training," in it he again emphasizes the lessons taught in his book. Recognizing that care should be taken not unduly to alarm the mother, Dr. Thomson points out that all she needs to be told about the present is that the child is unlike the ordinary run of babies in not being able, as yet,

to do certain common things as well as they do, and as to the future, that he will come to do many of these things, but that only time will show how far improvement is likely to go, and that this will depend largely on the amount of trouble she takes with him. Especially does he stress the fact that almost all these children are capable of being greatly improved in course of time by proper training, and made much happier than they could have been without it. It is true, as he points out, that only a few of the slighter cases will be self-supporting when they grow up, but many will be able to do work of some kind, and, though this may not support them, it will have the advantage of keeping them busy, and contented. The emphasis here given to the value of early training in the case of defectives must also be applied to the period when these children reach school age. It often happens that a mother does her best with her child as a baby, but finds that no provision is made for its subsequent training, though this is actually as essential as in the case of normal children. Where centres have been established by the Voluntary Association for Mental Welfare it has been found that even "incurable" children are capable of learning a good deal in the way of manners, collective games and singing, and simple occupations. The training of high grade defectives and backward children is probably of even greater importance from the social point of view. The presence of a defective in an ordinary class is not advantageous to the child, his classmates, or the teacher. The defective is liable to be afflicted with a permanent sense of inferiority, and is, furthermore, compelled to spend several of the most important years of his life being taught what he is incapable of learning. Under such conditions there is every chance that the child will become wayward, troublesome, and even vicious, whereas if he is taught in a special class or school where those aptitudes which he happens to possess are developed, he will feel that he is capable of something, and will be much less likely in subsequent years to swell the ranks of the paupers and delinquents. The money and care expended on the mentally defective are not wasted, and though they cannot lead to a cure, they will do something to prevent these cases from developing into a menace to the community.

DOZING AT THE WHEEL

The tragedy of the death of Mr. Hamilton Drummond, surgeon at the Royal Victoria Infirmary, Newcastle, calls attention to a possible cause of some mysterious motor accidents. Mr. Drummond died from injuries received through the overturning of the car he was driving. The car swerved suddenly to the left, and ran into a gate. At the coroner's inquest it was reported that before he died Mr. Drummond said, "I dozed over, pulled in, could not recover. Have you ever had that experience? I have done this before, but once too often." Such an accident may easily occur with an overtired driver, soothed to greater somnolence by the rhythm of the engine and the monotonous grind of the gear. A doctor tells us that on one occasion while his new car was being driven to London by an employee of the manufacturers, he suddenly noticed that the driver was slipping down between the steering pillar and the seat. The man was asleep, he explained the occurrence by stating that he had been driving for three days and nights! Medical men who drive their own cars must be more liable than most people to the risk of falling asleep at the wheel, since they often have many long days of tiring work. Since Mr. Drummond's death other medical men have told us of their terrifying experiences in dozing while driving, and more than one has said that when he found the inclination to sleep overpowering he pulled up in some safe place by the side of a road and took

a short nap. It seems possible that many of the fatal accidents which, being unaccountable, have been attributed to a burst tyre or to some derangement of the steering apparatus, may really have been due to the driver falling asleep, the evidence of its effect in causing accidents is sufficient to suggest that motorists who are very tired would be wise to refrain from driving on monotonous country roads.

SIR WILLIAM HAMER

We greatly regret to learn that, on grounds of health, the services of Sir William Hamer will no longer be available to the County Council of London. He became assistant medical officer under the late Sir Shirley Murphy thirty-three years ago, and succeeded to the principal post on the retirement of his chief. During his period of office the public health functions of the County Council have been very greatly developed. When he began the accommodation for the health staff consisted of two or three rooms of very modest size in an upper floor of a house adjoining St. Martin's Church, and there was the meagre nucleus of a department. Now it occupies a large space in the notably handsome building on Thames side at Westminster Bridge, the increase in the space it occupies only corresponds with the increase in its activities, which now include among many other things, the whole work of school medical inspection and treatment in the area of the metropolis. The annual reports of the retiring Chief Medical Officer have constituted a notable part of the current health literature. He is in the best sense of the word an epidemiologist, and his published studies in that science are read with the keenest interest, including as they do thoughtful discussions of such subjects as the agencies involved in the spread of enteric fever, and the interrelationships of differently named diseases, like influenza and the group of cerebral infections of which encephalitis lethargica is at present the most prominent member. At meetings where bacteriologists, statisticians, clinicians, and epidemiologists foregather in friendly controversy, Sir William Hamer's contributions to debate have always been a notable feature, and the discussions have never been characterized by monotonous unanimity. It is sincerely to be hoped that in the leisure or well earned retirement his health will be speedily and fully restored—he is still far short of being an old man—and that he will devote some part of his time to the elaboration and exposition of his views on the root problems of public health from the scientific side, and on administration from the side of practical experience.

THE LATE DR HERBERT WILLIAMSON

It is proposed, with the approval of the Medical Council of St. Bartholomew's Hospital, that a memorial to the late Dr. Herbert Williamson be established at St. Bartholomew's. The form which the memorial takes must depend upon the sum subscribed, but it is hoped that a sufficient amount may be secured at least to endow a bed in the Obstetrical and Gynaecological Department in which he worked. Subscriptions from Dr. Williamson's former colleagues, students, and friends should be sent to Dr. Barris, 50, Welbeck Street, London, W.1.

We announced some time ago that there was a movement on foot to obtain a portrait memorial to Sir John MacAlister, who recently resigned the office of secretary of the Royal Society of Medicine after holding it since the formation of the society, which was achieved largely through his efforts. We are informed that the fund now amounts to £615, subscribed by 307 individuals.

Scotland.

EDINBURGH MEDICAL GRADUATION

SOME two hundred students, of whom about one-fourth were women, graduated in medicine at the University of Edinburgh last week.

Professor G. M. Robertson acted as "promoter" and gave the address to the graduates. After depicting the necessity for examinations, he said that it was strange that no test was applied to that which was the master-key to success in a physician—namely, "personality." Personality was described by some in poetical language as personal magnetism, by others it was regarded as a miraculous gift of healing, he went on in humorous vein to compare this gift with magic. There was no charm of magic in the University of Edinburgh, although, he said, Sir Walter Scott informed us that at the University of Toledo there was a charm of incantation. If King James VI, who founded the University, had been present in Edinburgh last week when Wemyss was opened and had heard the voice of the King addressing the people from the in his modern development of electricity, he would certainly have regarded this as a manifestation of magical character. In the Faculty of Medicine magic under a disguise was also to be found, the prescription of life by insulin, the painless sleep of chloroform, and the protection of millions of people from typhoid fever, were in a sense magical. Magic consisted in a certain habit or attitude of mind towards inexplicable phenomena, and no educated person now believed that the applications of physics were magical, but the symptoms of disease readily lent themselves to treatment by magical methods. Pain was the basis of every symptom, misery and discomfort were merely lesser varieties of it, and pain was simply a state of mind like the sensation of colour. Pain was sometimes called real and sometimes imaginary, but to the patient both forms were real and both were inenarrable to treatment by mental suggestion, whether magical or otherwise. A patient desiring treatment of a magical kind might go to a Christian Scientist, he might consult a plausible charlatan, or he might seek the vendor of a secret nostrum. In many cases he would benefit, and as honest seelers after truth those he was addressing must face the facts. Christian Science was a very simple therapeutic system from which diagnosis was excluded and which employed one remedy. Yet it had succeeded in founding cathedrals and in comforting millions. Had the medical profession, like Mathra, been careful and troubled about many things material, but missed the one thing psychic that was useful? If a patient consulted a regular practitioner of medicine almost inevitably he would prescribe certain vegetable or mineral products, and the patient would derive benefit from the prescription. Drugs undoubtedly possessed pharmacological actions which were invaluable, but symptoms were mainly mental, and medicines depended largely for the benefit they conferred upon the confidence of the patient in the physician and faith in his prescription. What distinguished the doctor from the "healer" was his undeviating rationalism. Recognition of the mental element in disease was deficient, and he had a horror of introducing mystery into his treatment, even though his patients had not yet emerged from the darkness of superstition. It was not however in the alleviation of symptoms nor in the treatment of minor ailments that medicine was impressive, but rather in its confident challenge to the diseases that killed. During the lifetime of persons at present living the death rate had fallen from 22 per 1,000 to 12 and the expectation of life had risen from forty years to fifty-five. That was like the Prophet's promise to the dying Hezekiah: "I have heard thy prayer, I have seen thy tears, behold, I will add unto thy days fifteen years." Professor Robertson concluded by saying that the most valuable asset of the physician was personality. Its influence in sickness was mental healing, which was of the greatest value when trained and directed. The methods of such healing varied with age and sex, with race and religion and with circumstances but it was this possession that made medicine greater than science.

A previous graduation ceremony had been held on Wednesday, July 22nd, at which a number of distinguished men received the degree of LL.D. These included the Right Hon. J. Ramsay MacDonald, M.P., Mr. G. K. Chesterton, Dr. A. H. Freeland Barbour, Mr. Alexander Miles, F.R.C.S., and Sir Harold Stiles, K.B.L., F.R.C.S. The Honorary Graduates were entertained at dinner in the upper library of the University of Edinburgh on the evening preceding the graduation ceremony.

CONGRESS OF THE ROYAL SANITARY INSTITUTE

The thirty-sixth congress of the Royal Sanitary Institute was held in the Edinburgh University Buildings from Monday, July 20th, to Friday, July 24th. Some nine hundred delegates attended on the first day when an official welcome was given by Lord Provost Sir W. L. Sleigh and other municipal representatives. A public luncheon was held in the hall of the University Union, at which the Lord Provost presided, and in the evening the delegates met in the McKean Hall to hear the inaugural address of the Secretary for Scotland, Sir John Gilmour, who was president of the congress. The Marquess of Aberdeen presided. Sir John Gilmour observed that this was the first occasion upon which the Royal Sanitary Institute had held its annual congress in Edinburgh. He discussed various matters regarding the public health work of Scotland, and indicated some of the points in which the Scottish Board of Health was most actively engaged at the present time. These have been already summarized from the report of the Scottish Board of Health in the *BRITISH MEDICAL JOURNAL* of July 18th (p. 148).

On Tuesday, July 21st, over one thousand members, delegates, and associates attended the conference meetings. Sir George Newman, K.C.B., Chief Medical Officer, Ministry of Health, in his presidential address to the Sanitary Science Section, discussed the future of sanitary science. Reviewing the results since the passing of the Public Health Act in 1875 he said there had been a decline in the death rate from 21 to 12 in 1924, while in the same period the infant mortality rate, the most sensitive index of national health, was brought down from 149 per 1,000 born to 75. Expressed in another way, the expectation of life of every child born in Britain today was approximately twelve years longer than that of its grandfather. There had also been a great reduction in sickness and invalidity from certain diseases. There was still much that was anomalous, extravagant, and redundant as regarded views and authorities for dealing with health questions, and this led to ineffectiveness and waste. What seemed to be needed was a single unit of health government with necessary subcommittees for particular purposes.

Captain Elliot, M.P., commenting on the advances that had taken place in industrial hygiene, said that the employment of children was no longer a menace to the national health, and the conditions in factories and workshops were beyond all reckoning better than they were a few years ago.

Sir W. Leshe Mackenzie, LL.D., of the Scottish Board of Health, addressed a public meeting in the evening on the problem of psycho-physical fitness. Speaking on the causes of unfitness he said that some of these lay on the surface and were known to everybody. Every attack of disease meant a temporary or permanent increase of unfitness. He thought that two definite public movements were making a systematic search for unfitness: those were the child welfare movement and the medical examination and treatment of school children. Discussing the preservation of social fitness, the speaker said there was a great field in the psycho-neuroses for preventive and curative treatment, and in the segregation of the feeble-minded into proper institutions one great source of psycho-physical unfitness would be destroyed.

On Wednesday, July 22nd the meetings of the Sanitary Science, Personal and Domestic Hygiene, Sanitary Authorities, and Medical Officers of Health Sections formed the programme of business. Dr. Robert A. Lister, in his presidential address to the Medical Officers of Health Section, said the urgent need was for an entire medical profession trained in, interested in, and engaged in the practice of prevention of disease.

Dr. James Young (Edinburgh) read a paper in the course of which he gave a lantern demonstration of the micro-organism which he believes to be the cause of cancer. (See page 271.)

Lady Aberdeen discussed the question of personal health. Dr. Fremantle, M.P., appealed for a central directing policy in national health which would economize services and encourage private effort. Tuberculosis and the treatment of leprosy were discussed in the Sanitary Science Section. Dr. Archibald Leitch, director of the Cancer Hospital Research Institute, London, contributed a paper on practical measures which should be advocated for reducing the prevalence of cancer.

On Thursday, July 23rd, Prof. Sir Hudson Buxton delivered a presidential address to the Engineering and Architectural Sections, in which he discussed the problems of housing and transport. He considered that dwellings were as lasting and as substantial as those of brick. Dr. Gerald Leighton spoke on the necessity for a closer alliance between the veterinary and medical professions in his presidential address to the Veterinary Inspectors' Section.

On Friday, July 24th, the congress concluded. Counsellor Dr. F. G. Nasmith (Edinburgh), in a paper to the Maternity and Child Welfare Section, urged the necessity for providing beds for ante-natal treatment in maternity hospitals. At the Health Visitors' Conference considerable discussion took place in regard to the training of women for various branches of the nursing service.

During the congress a health exhibition was held in the Waverley Market, Edinburgh, which illustrated the evolution of modern sanitation and the present state of various agencies for the amelioration of the home and civic life.

Ireland.

A TUBERCULOSIS TOUR

Sixty months ago a reputation of the Tuberculosis Committee of the Belfast Corporation waited on the Prime Minister of Northern Ireland (Sir James Craig Bt, M.P.) to urge that some further efforts should be made to render available recent methods of treatment of tuberculosis. As an outcome of this meeting a medical commission was appointed to visit institutions and to report on various forms of treatment, including the Spaulinger and that by sunbath. This committee, which consisted of Dr. A. Trimble (Chief Tuberculosis Officer, Belfast), Dr. T. Houston (Chief of Clinical Laboratories, Royal Victoria Hospital, Belfast), and Dr. Norman Graham (City Bacteriologist), visited London, Paris, Geneva, Montigny, Frankfurt, Hamburg and Copenhagen in all of which places they were received with great kindness, saw many of the leading authorities on the subject, and were given opportunities of examining the methods, the statistics, and the results as far as available.

The report is now presented to the Tuberculosis Committee. Towards the end it states that in all the towns visited there was a recognized medical institute devoted to research and the investigation of disease and methods of treatment. This statement will be welcomed by those who have for years advocated, in connexion with the local university, the formation and equipment of such an institution. The members did not confine their attention to the one subject, but, as opportunities offered, took note of work being done on the blood, on cancer, and on other directions, also of the hygienic labours of the League of Nations.

The report is prepared for a lay committee, and so, it may be presumed, does not represent all the knowledge its members have gained or all the opinions they have formed. They were evidently impressed with Mr. Spaulinger and met many who had "formed a high opinion" of his methods and results but nowhere do they say that they were convinced as the profession is convinced, of the efficacy of antitubercular serum, or of salvarsan or its modifications. The same attitude is adopted as regards sunbathing which is now being tried in Belfast. When we remember the countless "cures" that have been

exploited in the past, the natural intermittency of tubercle, and the many undoubted cases of recovery without any treatment, we can appreciate the wisdom of the reports in a return of a verdict of "not proven, but" "well worth full investigation and trial." The profession in Ulster appreciate the warm sympathy and encouragement of the Prime Minister and Government of Northern Ireland, and its action in giving the financial sanction required for the expenses of the Commission, it is in keeping with the broadminded support of the many extensions of the University.

Correspondence.

CANCER AND THE FILTERABLE VIRUS

S.—I am not in a position to criticize the value of the discovery made by the help of Bismuth but I am sure that many of our profession have noticed for years past paper-much, to the effect that the cause of filterable virus is a cancer cell. I have not been able to repeat this as yet.

For some years I have been interested in the study of many of the known filterable bodies, especially the virus of vaccinia, variola, herpes, pemphigus, chicken, influenza, and possibly that from a common cold. All of these can be recognized when examined by direct ground illumination with as low a power as 1/3 inch objective and compensation ocular No. 12 or 18—1/2 inch, with a magnification of 350 to 550 diameters, in fact that is the method I have constantly used for at first determining the presence or absence. I have so far used chiefly Giemsa stained films and these have been subsequently examined with a good oil immersion objective—for example 1/10 or 1/12 inch under critical conditions and with suitable colour screens.

Anyone can prove for himself if a virus is to see the virus, say, of vaccine by taking a minute drop of serum from a vaccinated arm and spreading this is thick as possible on a slide or cover glass allowing it to dry, and then staining with Giemsa fluid or an old solution of methylene blue for some hours. The thinner the film the better the image and the less stained is the background.

In my experience after many months' work at these virus bodies with magnifications from 2,000 to 3,000 diameters, I should say there is very little difference in the appearance between the virus bodies of one disease and those of another. They may differ slightly in size, possibly a little in shape, the average size is about 0.2 to 0.3 μ in diameter. In other words, they are perfectly defined and definite bodies—not degenerate products as some would have us believe—but they have little or no individuality, and I very much doubt whether any increased magnification, or any increased aperture of the objective, or the use of light of shorter wave-lengths would render any material service in the elucidation of the nature in the differentiation of one species from another of these minute bodies. I am hoping that certain modification in the method of staining or more correctly methods of preparation, at which I am now working may perhaps give us a little more insight.

I would like to put on record here the very remarkable and original observations which my friends Mr. I. M. Nelson and Mr. Thot Mehlum, admittedly two of the finest microscopists in Great Britain, have made on the structure of the virus bodies. I sent to both of these observers carefully fixed and Giemsa stained films of the vaccine virus. They, use the finest apochromat objectives, Nelson a 1/12 in. of N.A. 14, and Mehlum a 1/8 in. of N.A. 142, with oil immersion condensers and suitable colour screens, and only the light from 1/2 inch wick of a paraffin lamp. Mr. Nelson pointed out that the vaccine bodies had a flagella-like appendage later, October 8th, 1922, on further examination he reports: "The germs in the vaccine virus are not isolated but are fixed to a very delicate mycelium, just like the tubers on a rhizome." Mr. Mehlum, independently, on October 25th 1922, says: "There is no doubt whatever that a great many vaccine bodies are fixed in long lines and curves to mycelial threads, as described by Nelson. Is it

not possible that the germs are really spores formed in the mycelium and that they break away from the mycelial threads when ripe?"

Nelson, writing on the virus bodies of influenza—film made from lung of a fatal case—says: "Minute germs, many on mycelial threads, not unlike those of the vaccine virus, but if my memory is right they were more on a plexus, whilst these were on isolated chains." My powers of microscopic vision are unfortunately not nearly so keen as either those of Nelson or Merlm, and up to the present time I can only see short thread-like appendages on a few of these minute bodies, but I would like to ask Mr. Brunard if his wonderful apparatus and special illumination has enabled him to see any such minute details on the so-called cancer virus—I am, etc.,

Bournemouth July 24th

ALFRED C. COLES

* Dr. Gordon's remarks in the Section of Pathology and Bacteriology at the Annual Meeting at Bath on July 22nd were reported last week (p. 192). The full text of his report will we understand, be published shortly by the Medical Research Council.

SIR,—Dr. Gie's recent investigations¹ have been of special interest to me, because I believe his virus will prove to be identical with the ultramicroscopic phase of the complex micro-organism which I described in 1921. This micro-organism I have obtained from a large number of cancers of all types. I have shown that the larger elements (cocci, bacilli, fungi) which soon appear in any ordinary culture medium containing a piece of cancerous tissue can be traced directly from minute elements, which emerge from the cells, or indirectly from an amorphous material, which escapes from the cells as globules and rods and which in this early stage is often curiously resistant to ordinary stains. This unstained "plasm" often first appears in and escapes from the dying cells as minute elements just on the verge of visibility. A study of these facts led me to write in 1922 that "the organism has, during its parasitic phase, acquired the faculty of infecting individual cells and of living in a sort of symbiotic relationship with the cells which it inhabits. This conclusion goes far to confirm the view which I advanced in a previous paper (1921) that the organism lives parasitically in a minute phase which is unveiled by ordinary methods of staining." The globules and rods can sometimes be seen to emerge from the cells with a cleanness that is diaphanous. The organized forms (cocci, bacilli, yeast) often spring from refractile elements which appear in and are detached from the globule and rod. Glover of New York and his colleagues have recently described a microbe which they have obtained from all types of cancer and whose general characters are similar to mine.

A remarkable feature of this micro-organism is that the alternative forms, although springing from one common stock, can pursue each an individual and stable life as cocci, bacilli, or yeast and they may resist any efforts to change them, although I have frequently, during five years' study, convinced myself that under certain conditions any one form can pass over into any other form. These facts are foreign to ordinary bacteriological teaching and have made my views incongruous to many bacteriologists, although there is a great deal of evidence in the literature to support them (Lohms, Mellon, de Negri, Hort, Almquist, etc.). It is, I believe, apparent from the recent literature that fixity of form in bacteria is illusory as a criterion of specific characters for, as Lohms, Mellon, I, and others have shown, the alternative phases of the same organism can often and probably usually pursue an independent true-type existence. It is sometimes urged that such a conception is opposed to the facts of biology. This is not so. It is opposed to much of the traditional teaching of bacteriology, but it is obviously in conformity with the great biological fact that a multitude of different cellular elements, each capable of independent propagation, are commonly derivable from one common germ-plasm. The further back we go in the world of life forms the more we find the differentiated cell assumes the multipotential characters of the original plasm. In the bacteria this retention would seem to be complete. The essential resemblance between the

primitive bacterial matrix and the germ-plasm of higher life led me to name the former the bacterioplasm.

The first indications of these facts in regard to the cancer parasite came to me when I discovered that "plasm" rod or globule, minute granule or thread (in this stage stillingly similar to Rickettsia), bacillus or coccus could apparently, depending on the culture medium and other factors, be derived indifferently from the cells of the same piece of cancer. The confirmation of these facts came with the discovery that from the same "plasm" all the different forms were derivable. In this stage the refractile granule is a common index. During this phase the germinating "plasm" is easily mistaken for masses of debris to which the bacterial forms have adhered. As Lohms has pointed out, in the past it has been commonly looked upon as dirt.

With the attention now being paid to the cancer parasite I feel forward confidently to an early confirmation of these views first published in 1921. For long I have been urging that a similar reorientation of the bacteriological mind would probably quickly resolve the difficulties surrounding typhus, influenza, small pox, etc. If it be true that Weigl, Bicin, and Fejgin have all succeeded in deriving the *Bacillus proteus* (X 19) commonly associated with typhus from the Rickettsia of typhus, we have the first augury of the unexpected facts which will transpire with the application of this broadened outlook. We can safely prophesy big developments along the same lines in the near future.

That familiar bacteria may possess a filterable phase is suggested by the work of Heymans (*B. anthracis*), Valtis, Vinnici, etc. (*B. tuberculosis*), Almquist (*B. typhosus*), Hort (*Meningococcus*), and Lohms. The very striking investigations of Lohms make it likely that all bacteria have a filterable mode of life, it may even be that this is the essential parasitic form of all bacteria—I am, etc.,

JAMES YOUNG

Edinburgh Aug 1st

CANCER BURIAL OR CREMATION?

SIR,—I am writing to urge that the profession should advocate cremation in cases of persons dead of cancer. I understand that cancer is now shown to be caused by a filter-passing germ. Now if a germ will pass through a porcelain filter, surely it will pass through any soil, either gravel, chalk, or clay, and will slowly percolate downwards until the deep water be contaminated.

Maeaulay, in his history, calculates the population of these islands in 1685 as about five million. We are now nearly forty million, which means that if by burial the deep water is contaminated, it is now nearly eight times more likely to happen than in the reign of Charles II.

May not the increase of cancer be due to this? Burial or cremation are essential for the disposal of the dead, but it cannot be pleaded for burial that it is an imitation of following of Nature's way of disposing of a dead body. I think it is quite possible that we are taking too much comfort from the old saying "Out of sight out of mind"—I am, etc.,

Yattendon Berk July 20th

F. A. BRODIE

COLLECTIVE INVESTIGATION OF RHEUMATOID ARTHRITIS AND ALLIED CONDITIONS

SIR,—After a long and pretty extensive experience I can say without hesitation that rheumatoid arthritis and allied conditions cause more human suffering and incapacity than that produced even by malignant growths.

It seems to me that their collective and intensive investigation might very well be undertaken with rather more hope of beneficial results than in the case of cancer.

No doubt the study of etiology and pathology should receive due attention but I do not think that it should be at all necessary to postpone the making of careful therapeutic experiments until all points as to nature and causation have been fully and finally settled. Of course, many such experiments have been made and are being made daily—and they will continue to be made. It would be necessary to collect and correlate the nature and results of past, present and future work carried on in special institutions as well as in general and special practice.

The sending out, the filling up, and the co-ordination of

Chambers of Medical Science and National Health Insurance
The Summer Time Bill was also read the third time and passed.
The Royal Assent has been given to the Mental Deficiency
Amendment Act and the Guardianship of Infants Act.

Chairman of Medical Service Subcommittee—Mr. Meller asked the Minister of Health whether he had received from the Insurance Committee for the County of London a representation protesting against the National Health Insurance (Medical Benefit) Amendment Regulations (No. 2) 1925 which provided for the appointment of the chairman of the Medical Service Subcommittee by the Minister of Health failing the unanimous vote of the subcommittee and further provided that such person might not be a member of the Insurance Committee. Sir Kingsley Wood replied that under the previous regulations the chairman of the Medical Service Subcommittee was required to be elected by the approved society representatives on the subcommittee and the of any selection by them by the neutral members of the Insurance Committee. No request for an amendment of the regulations had been received from any members of the House in London failure to find a chairman commanding the confidence of both parties led to the withdrawal of the representatives and the machinery for the investigation of complaints was brought to a standstill. A similar situation had arisen recently in Southampton. The amending regulations of 1925 arose out of the difficulty in London and represented a settlement which the Minister of Health understood to be agreeable to both parties to the dispute. The Minister had recently received representations from the London Insurance Committee against the new regulations but he could see no other method of preventing the recurrence in future of a deadlock in the administration of medical benefit and to the detriment of insured persons. On August 3rd Mr. Harney moved a resolution in the House praying that Regulation No. 2 of July 1925 be rescinded. Mr. Neville Chamberlain said he had taken part in the negotiation with the parties concerned and he had withdrawn the article in the regulation to which objection had been taken and to substitute other arrangements. The Minister of Health stated (August 3rd) that he was not prepared for the distribution of the Government's share of the cost of the National Health Insurance.

[illegible][illegible][illegible]

Account Haldane supported the bill which was read a second time the second reading of the Bill was postponed owing to an objection raised by the Duke of Devonshire and other members of the House of Lords in the Commons. Drafting changes made by the House of Lords in the Commons amendments to the Therapeutic Substances Bill were accepted by the House of Lords. Further progress with the Dangerous Drugs Bill was accepted by the House of Lords. In the House of Lords the Glasgow Act 1888 (Amendment) Order Confirmation Bill was read the third time and passed.

Further progress with the Dangerous Drugs Bill was accepted by the House of Lords on August 4th the Victoria Infirmary of Glasgow Act 1888 (Amendment) Order Confirmation Bill was read the third time and passed

regulations had been issued dealing with grinding, a frequent cause of silicosis, and regulations were under consideration for vehicle painting and the painting of buildings.

In answer to a question on August 3rd Mr G Locker Lampson (Home Office) said that he was advised that it was not necessary to extend the provisions of the Lead Paints (Protection against Poisoning) Bill to give protection against the dangers of poisoning incurred in painting whether from lead or other paints as there was no evidence of danger of poisoning from any paints other than those dealt with in the bill.

Scottish Estimates

On August 4th the Scottish Estimates were discussed in the House of Commons. Mr Selwyn Hughes raised the question of the treatment of inmates, and Mr S. Mitchell said that he was not satisfied with the present test for tuberculosis in cattle, which could be easily defeated.

Sir John Gilmour, Secretary for Scotland, replying to the debate, announced that he proposed to set up a committee on the employment of juveniles in Scotland. The more he probed into the housing problem the more he realized the slow progress that had been made and that some other methods must be found. The greatest difficulty lay in the shortage of building labour. The construction of 300,000 steel houses was being held up because of trade union rates or wages or this or that trade union condition. The problem could only be solved by the combined effort of masters, operatives, local authorities, and the Government.

Mr Wheatley said it was admitted that the highest death rate in Scotland was caused by housing conditions inferior to those existing in England.

Dr Elliot (Parliamentary Under Secretary for Health Scotland) briefly replied.

Smallpox and Vaccination.—Answering Mr Brod Mr Neville Chamberlain said that of the 16 fatal cases of smallpox among vaccinated persons during 1922-1923 and 1924 only one was under the age of 35, while of the 22 fatal cases among unvaccinated persons 7 were in infants under 1 year and in children between the ages of 1 and 9. Of the fatal cases amongst vaccinated persons only one had been revaccinated and it was doubtful whether in this case the disease was smallpox. The remaining 15 cases had been vaccinated in infancy. In his opinion these facts showed the importance both of infant vaccination and of revaccination at appropriate ages. The Ministry of Health had never carried out experiments to ascertain how frequently vaccination could be repeated in the same individuals. He had no authority to arrange for such experiments nor did he think they would serve a useful purpose.

Deaths attributed to smallpox.—On August 4th Mr Brod asked the Minister of Health whether the Registrar General would revise his figures for 1924 in regard to smallpox deaths in the light of the information given in the recent report of Sir George Newman in which five of the smallpox deaths were transferred to other classifications, it being the opinion of the certifying doctor that smallpox was not the cause of death. Mr Neville Chamberlain said he understood that in the case of all the deaths in question smallpox was certified by the certifying doctor as being one of the causes of death. In such cases the selection from among several certified causes of the particular cause under which the death was classified for statistical purposes was governed by general rules based upon international agreement which in this country provided that deaths should be classed as smallpox if this disease was included among the certified causes. He saw no reason for revising the classification in the case of these particular deaths, especially since full information regarding them was given in the Chief Medical Officer's report.

Accidents in Mental Hospitals.—On July 27th Sir Kingsley Wood informed Mr Saltsvala that the Minister of Health was not prepared to give general instructions that in the event of a patient in a mental hospital meeting with injury the guardians of the particular union or parish to which such patient was chargeable should be immediately notified of such injury so that they could, if considered desirable, have such patient visited. Any request from a board of guardians to be represented at an inquiry held either by the Visiting Committee or the Board of Control would be considered on its merits in each particular case.

Poison Gas.—On August 4th Sir L. Worthington Evans (Secretary for War) in reply to Mr Cecil Wilson who asked whether the Committee of Imperial Defence had come to any decision as to the methods to be taken for the protection of the civil population against poison gas said that consideration of this question was progressing but he could not say when it would be completed.

Hospital Clothing.—The Minister of Pensions informed Mr W. Baker on August 4th that a rule was in force throughout all the hospitals of the Ministry that patients were expected to wear special hospital clothing. This rule which had been repeatedly considered had been found both by himself and his predecessors to be of material advantage in the interests of the patients and of their treatment.

Nursing Homes.—Mr Neville Chamberlain informed Mr Cooper Pannett that the Government did not intend to set up till after the recess the proposed Select Committee to inquire into the registration of nursing homes. The committee would no doubt consider the question of inviting evidence from the British Medical Association.

Notes in Brief

The circular letter of the Ministry of Health calling attention to the Lunacy Act of 1892 does not contemplate—nor has the

Minister of Health any intention of allowing—the housing of lunatics in the same premises as normal old people.

In 1922 there were discharged from the army 277 men on account of tuberculous disease, 236 in 1923 and 193 in 1924.

Mr Neville Chamberlain states that most sanitary authorities have made arrangements for the services of a veterinary surgeon for the inspection of cattle when occasion demands.

The Ministry of Pensions state that over 1,500 medical boards have been held in the London and Portsmouth districts during the past three months.

Provision for inquiries into road accidents is made under the London Traffic Act in regard to London, and the extension of some of the similar powers to the rest of the country is under consideration. Legislation for the better regulation of public service vehicles will be introduced as soon as possible.

Obituary

J. S. KESER, M.D., F.R.C.S.

Formerly Physician to the French Hospital, London.

Those who knew him died in London in the last decade of the last century will keep with regard to the death of Dr J. S. Keser. It occurred some six months ago, but has only just come to our knowledge. He had been ill for two years, and towards the end suffered much.

He received his early education in arts and science in Lausanne, graduated M.B. Geneva in 1877, and M.D. Bâle in 1880. He studied for some time at St. Thomas's Hospital, and took the diploma of F.R.C.S. in 1880, in 1884 he became F.R.C.S. England. He was physician to the French Hospital in London, and enjoyed a large practice, especially among the French-speaking colony in London. He had an attractive personality, he made friends easily, and always retained them. He was the correspondent of the *Semaine Médicale*, which under Dr. de Maurins (who was both editor and proprietor) won a high place among French medical journals and had a large circulation. It had itself out to report the meetings of societies and associations, and for a good many years Keser regularly attended the annual meetings of the British Medical Association.

In 1899 he was threatened with loss of sight, and made up his mind to retire. After a year's rest he was restored to health and was able to indulge his hobby, which was Greek archaeology, by extensive travel in Greece and the Near East. Afterwards he settled in the outskirts of Geneva and lived a life of lettered ease until it was rudely interrupted at the outbreak of war, when some hundred thousand miserable refugees, expelled from the invaded parts of France, passed through Geneva. He was placed at the head of the dispensary where some ten thousand persons were treated, many of them reduced to a shocking condition by the cruel treatment they had suffered at the hands of the Germans. It was a terrible experience for a man of Keser's cultivated mind and sensitive nature. Later the hordes of refugees were succeeded by other hordes carrying sick and wounded soldiers from France to Germany and the reverse, hundreds of volunteers were enlisted under the Red Cross and the work went on for years, involving great exertions and many hardships. All through he was unwearingly helped by his wife, with whom in her great loss all Keser's surviving English friends will sympathize deeply.

LIEUT.-GENERAL SIR W. LAUNCELOTTE GUBBINS, K.C.B.

Late D.G.A.M.S.

LIEUT.-GENERAL SIR WILLIAM LAUNCELOTTE GUBBINS, K.C.B., a former Director General of the Army Medical Service, died at Westgate from the effects of a cycling accident, on July 8th, aged 75. He was the second son of the late Chancellor the Rev. George Gubbins, M.A., of Maidstone, and of Kilperstone, co. Limerick, and was educated at Trinity College, Dublin, where he was Baccalaureus Smith Scholar, and graduated M.A., M.B., and M.Ch., with honours in history and literature, in 1872. He received the honorary degree of M.D. from his university in 1912, and the honorary F.R.C.S.I. in the following year. He entered the army as surgeon in September, 1873, attained the rank of colonel, by special promotion for

service in South Africa, in November, 1900, became surgeon-general on August 27th, 1903, and Director-General, with the rank of lieutenant-general, on March 6th, 1910, succeeding Sir Alfred Keogh in that post. He retired on June 1st, 1914, just before the beginning of the war, when he was succeeded by Sir Arthur Sloggett.

He had a distinguished record of active service, beginning with the Afghan war of 1878-80, in which he served with the 5th Northumberland Fusiliers—the 'Lighting Fifth', afterwards, on the staff of Lieut-General Sir F. Maude, V.C., he was present in actions in the Bazu Valley, and in the Mohmand and Ghilgai expeditions, receiving the medal. He also served in Egypt in 1882, and in Burma in 1885. From 1894 to 1899 he held the post of assistant director of the Army Medical Service at the War Office. He served in South Africa from 1899 to 1901 as P.M.O. of the 6th Infantry Division, and afterwards of the Pretoria District, with the local rank of colonel, took part in the relief of Kimberley, in operations in the Orange Free State, including the actions of Paardeberg, Poplar Grove, and Drifontein, and in the Transvaal. He was mentioned in despatches in the *London Gazette* of February 8th, 1901, received the Queen's medal with five clasps, and was specially promoted to colonel. He was P.M.O. of the Home District in 1902-3. On promotion to surgeon-general he was posted to India where he was P.M.O. of the Western (Bombay) and Eastern (Lucknow) Commands successively. He was P.M.O. of H.M. Force in India from 1906 to 1908. From 1908 to 1910 he served as Deputy Director-General of the A.M.S., prior to his promotion to Director-General.

After his retirement he was again employed, in the recent war, chiefly in connexion with the Red Cross Society. He received the M.V.O. in 1902, the C.B. in 1903, was appointed honorary surgeon to the King in 1909, and was promoted K.C.B. in 1911. He received a Distinguished Service Pension at the end of the war. He was a Commissioner of Chelsea Hospital and a justice of the peace for Surrey. In 1885 he married Florence Muguet, second daughter of the Rev. H. Mugg of Huntspill and Winford, Somerset. He had lost two sons, but is survived by his widow and one daughter.

**MAJOR GENERAL SIR OLIVER JULIAN, K.B.E.,
C.B. CMG,
Army Medical Service**

MAJOR-GENERAL SIR OLIVER RICHARD ARCHER JULIAN, K.B.E., C.B., CMG, Army Medical Service (retired), died at South Molton, Devon, on June 13th, aged 62. He was born at Gillingham, and was educated at St. Bartholomew's Hospital; he took the M.R.C.S. and L.S.A. in 1885, and the L.R.C.P. Lond. in 1886, he obtained the D.P.H. of the London Colleges in 1905. He entered the army as surgeon in February, 1887, he was made brevet lieutenant-colonel in July, 1908, but did not reach the rank of lieutenant-colonel in the regular line of promotion till August, 1911, when he had twenty-four and a half years' service. He was promoted to colonel in the long war promotion list of March 1st, 1915, received the temporary rank of surgeon-general in June, 1917 and became major-general in April 1918. He retired on March 22nd, 1921. He served in the South African war for the whole three years (1899-1902), taking part in the operations in Natal, including the defence of Ladysmith, and the actions at Tlanya, Lombard's Kop, and Laing's Nek, and in the Transvaal, including the actions at Belfast and Ladenburg. He was mentioned in despatches in the *London Gazette* of February 8th and September 10th, 1901, and received the Queen's medal with four clasps, the King's medal with two clasps, and the C.M.G. He next saw service on the North-West Frontier of India in 1908 in the Mohmand and Zakka Khel campaigns of that year including the actions of Matti and Kughra, was mentioned in despatches in the *London Gazette* of August 14th 1908 and received the frontier medal with clasp, and was specially promoted brevet lieutenant-colonel from 1913 to 1915. He was physician and surgeon to the Royal Hospital, Chelsea.

During the recent war he served in France as a D.D.M.S., was mentioned in despatches in the *London Gazette* of

January 1st and June 19th, 1916, and received the C.B. in 1916, and the C.B.E. in 1919. He succeeded Surgeon-General Henthaw as D.D.M.S. of the Western Command in 1918, and in the following year was sent as D.D.M.S. to Mesopotamia, receiving the K.B.E. for his services there, in February, 1921.

**EVAN EVANS, M.B., B.Ch., F.R.C.S.,
Llanelli**

We regret to record the death of Dr. Evan Evans at Llanelli on July 18th, in his 72nd year. Dr. Evans received his medical education at Cambridge and St. Mary's Hospital; he graduated M.B., B.Ch., and obtained the diploma of M.R.C.S. in 1886. In 1888 he obtained the D.P.H., and in 1894 the F.R.C.S. For the last forty years he had been medical officer of health to the Llanelli Rural District Council and Poor Law officer to the Llanelli Union. He was also engaged in general practice, and was an eye specialist under the Pensions Board for West Wales. His other appointments included those of medical referee under the Workmen's Compensation Act, and lecturer and teacher under the Midwives Board. Shortly after settling in Llanelli he became associated with the local volunteer corps, and subsequently held a commission in the 4th Battalion Welch Regiment three years ago. He retired with the rank of surgeon lieutenant-colonel. He was the pioneer of ambulance work in Llanelli, and held his first ambulance class so long ago as 1887. He was appointed by the St. John's Ambulance Association to be commissioner for the county, and in 1921 became an honorary associate of the Order. In 1924 he was invested by the King as a Knight of Grace. Always a strong supporter of the British Medical Association, he was an ex-chairman of the West Wales Division, and ex-president of the South Wales and Monmouthshire Branch. He leaves a widow, one son, who is in practice at Westcliff-on-Sea, and three daughters. The funeral was held on July 22nd, with full military honours, officers of the St. John's Ambulance Association acting as bearers.

THE LATE DR. R. M. BEATON

'A.B.' sends the following further tribute to Dr. R. M. Beaton, of whom an obituary notice, embodying a tribute from Sir Alexander Houston, was published last week (p. 237).

Beaton was a strong man and in consequence made enemies as well as friends. His convictions lay deep and he was prepared to sacrifice almost anything to them. Years ago, as a practitioner, he was almost a phenomenal success coming to London (Aberdeenshire was his home) as he did without friends or money, merely settling in St. Pancras; he was able, after something like fifteen years, to retire from practice and enter public life. But with the controversy over the Insurance Bill he quickly identified himself again with his profession dominating his Division (the St. Pancras and Islington) whose chairman he became and which he represented at Representative Meetings. He was chosen by the Representative Body as one of five to interview the Chancellor direct. His Division gratefully recognized these services and held in his honour a dinner, at which some beautiful silver plate was presented to him. Although in debate he struck hard, even remorseless, it was not before he had given long and temperate thought to his matter. And in his friendships, loyal and deep as they were it would not escape one that here was a man in whom without doubt were the elements of greatness.

We regret to record the death of Dr. JOSEPH BOYER SIDBALL, at Great Malvern, on July 4th, at the age of 85. Dr. Siddall received his medical education at St. Thomas's Hospital where he obtained the diplomas M.R.C.S. Lond. and L.S.A. in 1864. He then went to Aberdeen University and in 1865 graduated M.D., C.M., with the highest honours. In 1876 he obtained the D.P.H. Camb. Dr. A. C. Deveraux writes Dr. Siddall was in the real sense of the phrase a pioneer of medicine, for in 1868 he went to Japan as medical officer to the British Legation. There

Awards and appointments

The Baly Medal was awarded to Professor R. Magnus of Utrecht on the recommendation of Council.

On the recommendation of Council Sir Frederick Andrewes was reappointed a representative on the Executive Committee of the Imperial Cancer Research Fund.

Harleian Oration

The President announced that he has appointed Sir John Rose Bradford K C M G , C B C B E , M D , to deliver the Harveian Oration in 1926

ROYAL COLLEGE OF SURGEONS OF ENGLAND

AN ordinary council meeting was held on July 30th, when the President, Sir John Bland Sutton was in the chair.

Professor Alexander Primrose C B was introduced and admitted a Fellow of the College

Diplomas of Membership were granted to 235 candidates and diplomas of Fellowship to 3 candidates

Diplomas were granted jointly with the Royal College of Physicians in Public Health to 14 candidates in Tropical Medicine and Hygiene to 28 candidates, and in Ophthalmic Medicine and Surgery to 17 candidates.

The names of the successful candidates are published in the report of the committee of the Royal College of Physicians of London published in this issue.

Post Graduate Study and the Fellowship

The following resolution adopted at the annual meeting of the Canadian Medical Association was referred to a committee for consideration:

That this Council puts itself on record in expressing its unanimous desire and approval of establishing such means as may be necessary for the purpose of facilitating for our Canadians by post graduate study and examination the obtaining of the Fellowship of the Royal College of Surgeons of England

Supplemental Charter

The terms of a petition for a Supplemental Charter were taken into consideration and approved and it was decided that the further steps to be taken in the matter should be considered at the quarterly meeting of the Council in October. The proposed Supplemental Charter is in general terms to enable the Council to make improved arrangements for certain examinations. In accordance with this object it is proposed to give the Council power to increase the number of members of the Court of Examiners and to give greater freedom in the selection of examiners for the Licence in Dental Surgery. It is also proposed to admit women Fellows and Members of the College and

Licentiates in Dental Surgery on the same terms and conditions as men and with the same rights and privileges, and to effect certain minor adjustments.

SOCIETY OF APOTHECARIES OF LONDON

Medical News.

WE have on several occasions called attention to the high price at which the Registrar General's *Statistical Review* is issued. The Registrar General, we understand, has himself regarded the price with dissatisfaction, and it has now been found possible to make a special offer of the two parts, "medical" and "text" to public health authorities and officers, at the price of 12s 6d a year instead of £1, on certain conditions. A circular has been issued by the Minister of Health to public health authorities, boards of guardians, and insurance committees announcing this and stating the conditions, which include a promise of a subscription for at least five years. The circular is accompanied by a memorandum by the Chief Medical Officer of the Ministry of Health.

THE King and Queen visited the Royal Society in the afternoon of July 22nd, before the annual ladies convocation that evening, and were received by the President, Sir Charles Sherrington. They saw many of the exhibits arranged for the evening, and attended a lantern lecture by Mr F E Smith, Director of Research at the Admiralty, upon the subject of navigational devices. On July 24th Sir Walter Fletcher, by command, presented Dr W E Gye and Mr J E Barnard to the King.

The Minister of Health and the Secretary for Scotland have appointed a committee to inquire and report whether any amendments are required in the Local Government and Other Officers Superannuation Act, 1922, in particular (a) whether it is desirable that the scheme of superannuation established by that Act should now be made obligatory on all local authorities, and (b) whether that scheme should, with or without modification in respect of particular classes of officers, be made applicable to all persons in the employment of those local authorities, other than school teachers and police. The chairman of the committee is Sir Amherst Selby Bigge, Bt, KCB, and Dr Drummond Shiels, M.P., is a member.

THE Fellowship of Medicine announces that the Queen Mary's Hospital, Stratford, will hold a general course in medicine, surgery, and the special departments from August 24th to September 5th, with practical study in gynaecology and obstetrics. On September 7th an operative surgery course commences at the Seamen's Hospital, the course will last five weeks with four meetings weekly. On September 21st, at the Brompton Hospital a two weeks course in pulmonary diseases begins. There will be an afternoon course with evening clinics at the Blenheim St. Hospital from September 7th to 19th. At the Infants Hospital a course of instruction will be given from September 7th to 19th in the latest methods of treating infantile ailments. The Royal Westminster Ophthalmic Hospital has arranged a course from September 7th to 26th, and there will be an intensive course in general medicine, surgery, and the specialties at the Westminster Hospital from September 21st to October 3rd. A series of lecture demonstrations in electrotherapy will be given on Wednesdays, beginning September 23rd, at the Royal Free Hospital. Copies of the syllabus of these courses can be obtained from the Secretary at No. 1, Wimpole Street W. 1.

The annual congress of the French Society of Oto Rhino Laryngology will be held from October 12th to 17th, at the Faculty of Medicine in Paris, under the presidency of Dr Bimel of Bordeaux. The congress will discuss latent otitis in children and the syndrome of the sphenopalatine ganglion, further information as to this congress can be obtained from the general secretary, 216, Boulevard St-Germain, Paris 7^e.

THE twelfth annual Congress of Hygiene will be held at the Institut Pasteur, Paris, under the presidency of Dr. Laveran from October 19th to 23rd when the following subjects will be discussed: (1) Is syphilis tending to disappear? introduced by Professor P. Auriol of Strasbourg; (2) standardization of the methods of bacteriological analysis of water, introduced by Dr. Rochoux of Lyons; (3) epidemiology, geographical distribution, and prophylaxis of undulant fever, introduced by Dr. Baruet of the Institut Pasteur; (4) experimental hygiene and laboratory research introduced by Dr. Dujardin de la Riviere; (5) general and social hygiene, introduced by Dr. Ott and Biran; (6) sanitary hygiene, introduced by Dr. Dequidat. Further information can be obtained from M. Bossu, 142 Boulevard Montparnasse, Paris XIV.

THE seventh congress of the French Society of Otho-pedies will be held in Paris on October 9th when the following subjects will be discussed: Pulmonary treatment of inveterate congenital dislocation of the hip introduced by M. Lanee; congenital club hand and paralytic club hand introduced by M. Roche of Bordeaux.

THE second Latin American Odontological Congress will be held at Buenos Aires in October and in international odontology exhibition is being organized.

THE congress of French speaking gynecologists and obstetricians will be held in Paris under the presidency of Dr. Sneyers from October 1st to 3rd when the following subjects will be discussed: the biological action of the corpus luteum and the interstitial gland of the ovary by Professor Schiele of Strasbourg; tumours of the broad ligament, by Professor Torquero of Montpellier; and Dr. Crousse of Brussels introduces for poliovirus, by Professor Romer of Lonsanno and Dr. Le Loric of Paris. Further information can be obtained from M. Proust, 2 Avenue Hoche Paris.

THE Zanon Ophthalmic Institute of Milan has offered a prize for the best essay published in 1925 on the experimental and clinical aspects of myopia.

AT a meeting attended by Dr. Cann, director of the European Mission of the Rockefeller Institute Professor Brumpt member of the Academie de Medecine and Dr. Serri senator of Corsica it was decided to found a malaria research laboratory at Bastia (Corsica). The expenses will be defrayed by the Rockefeller Institute.

THE Royal Free Hospital has received a gift of £2,000 from an anonymous donor for the enlargement of its light treatment department.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**

OFFICIAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish their names not to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles, published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, **British Medical Association House, Tavistock Square, W.C.1** on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the **JOURNAL** should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the **BRITISH MEDICAL ASSOCIATION** and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9361** 9662 9363, and **9664** (national exchange four lines).

THE TELEGRAPHIC ADDRESSES are **EDITOR OF THE BRITISH MEDICAL JOURNAL** (Literary Digest) London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advisement etc.) **Antislave Westcott** London.

MEDICAL SECRETARY **Medecina Westcott** London. The address of the Irish Office of the **British Medical Association** is 16 South Frederick Street, Dublin (telegrams **Brit Med Assn**). The address of the Scottish Office is 6 Drumshagh Gardens, Edinburgh (telegrams **Brit Med Assn**). The address of the Dublin Office is 4361 Central.

QUERIES AND ANSWERS

DR. J. DONALD (Glasgow) writes: I now wonder whether any experiments on animals have been made in this country by the intravenous injection of the local methyl propyl carbonyl methane?

A CORRESPONDENT asks whether there are any institutions in England where natural and artificial sunlight treatment can be given to a child suffering from chronic nerve trouble. She does not wish to enter a sanatorium for tuberculosis.

SUBNOCTURNAL TEMPERATURE. DR. S. V. H. TAYLOR (Middlesbrough) writes: I have written to the **BRITISH MEDICAL JOURNAL** July 2nd p. 184 asking for advice about subnormal temperature. The patient is otherwise fairly fit. I am inclined to ask two questions. The first is: Why worry if the individual has experienced in that often this is an average ten minutes and one of the 15th. Month temperatures taken for a minute are generally about this level in health especially if taken in cool weather and after a person has been inactive. An accurate reading of the body temperature is best taken in the rectum or at least by passing a good stream of urine on to the bulb of the thermometer.

LETTERS, NOTES ETC

SLEEP AND SLEEPINESS

DR. H. WILLIAMS (Birmingham) writes to express the opinion that Dr. I. H. Simmons in his article on sleep in our issue of May 9th did not attribute sufficient importance to the part played by the eyes in inducing sleep. In the course of his lecture Dr. Williams made the following observations: The feeling of sleepiness apart from the sensation which leads to yawning—a heaviness of the lid than in any other part of the body—is a heaviness of the lid. This is of practical importance in the induction of sleep. One of the commonest impediments to sleep is an overactivity of the mind during the last of the morning. This enema of mental material must be effectively counteracted by the following procedure: open the eyes wide keep them open and stare into the distance resist and continue to resist the increasing tendency of the lids to close. Consciousness is thus centred in this physical effort and the sense of eye weariness which supervenes while awake is an important element in sleepiness over which I think is an important element in sleepiness. The power of the overactive mind is side-tracked into oblivion. The power of habit is immense. Contact with the pillow should normally invite sleep. It is he adds important that the bladder of which we become empty even half a pint of urine in the bladder of which we are normally unconscious may with some he the last straw in maintaining wakefulness. As the bladder fills more rapidly while awake than asleep if one has lain awake for an hour double this quantity may have collected according to the amount of fluid taken before retiring. Thus an old Dublin doctor specific for insomnia was—Get up and pass water. There is further no more potent soporific than a mild degree of bodily fatigue and for those who cannot take a brisk walk or gentle run of a mile or so just before retiring to bed produces a very sound sleep which is profoundly restful.

DRIVING A CAR

ON *Driving a Car* the *British Motorist* is an extremely well set up advertisement of the *British Petroleum* as a petrol. On each left hand page of the book is an illustration as artistic as the subject will allow of some portion of the oilfields or works from which the *British* petrol is produced. Each right hand page has an illustration in bold design of some portion of a motor car to which is attached a hint on the proper care or the proper use of the part. For the new motorist the hints will be most useful. He will learn the meaning of choking the engine the disadvantage of overloading the correct method of braking safe method of starting the clutch while the *British Petroleum* Company will endeavor to persuade him that all these matters are dealt with best by the use of their petrol. Copies of the book may be obtained free on application to the *British Petroleum Company Ltd*, Britannic House, Moorgate, L.C.2.

ROAD PLANS

THE *Dunlop Rubber Company Ltd* have now issued the third volume of their series of provincial road plans. On the *London*, produced by *Ed J. Broom* and *Company Ltd* of Cheltenham price 6d. It shows the old coaching highways to Bath and Bristol which the rise of the motor car has brought back to life. It shows also the road from London to Milford Haven with Oxford the Cotswolds the valleys of the Thames Severn and the towns of Wales. There are six other plans of Cardiff Swansea Reading Oxford Bristol and Bath Central London and the way out. The book includes forty-eight strip maps adorned with thumb nail drawings.

MOTOR TOURS

AS evidence of the increasing popularity of motor touring the Automobile Association states that this summer it is issuing specially prepared routes and tours to members at the rate of over 1,000 miles a minute.

VACANCIES

NOTIFICATIONS of offices vacant in universities medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 34 35 38 and 39 of our advertisement columns and advertisements as to partnerships assistantships, and locum tenencies at pages 36 and 37. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 64.

British Medical Association.

PROCEEDINGS OF SECTIONS AT THE ANNUAL
MEETING, BATH, 1925SECTION OF OBSTETRICS AND
GYNAECOLOGY

Lady BARRITT, C B E, M D, M S, President

DISCUSSION ON
MALIGNANT DISEASE OF THE PELVIC ORGANS

OPENING PAPERS

I—B P WATSON, M D, I R C S F,

Professor of Midwifery and Diseases of Women, Edinburgh
University

THE PROBLEM OF CANCER OF THE UTERUS

When I was honoured by the invitation of the President and officers of the Section to initiate the discussion on malignant disease of the pelvic organs by saying something on the problem of cancer of the uterus I hesitated to accept because it seemed that nothing new could be said on the subject. On reflection, however, I realized that, as with every educational effort, constant reiteration, even to the point of boredom, is necessary if the public and the profession are to be thoroughly convinced of the responsibility which rests upon patient and doctor alike in the effort to diminish the great loss of life resulting from this disease. That proper education would result in such a diminution has long been realized. That it is not an accomplished fact is the justification for the present communication.

Incidence of Cancer of the Uterus

The toll that cancer of the uterus takes of the population of the world is enormous. Out of a total of 25,637 deaths from cancer in females in England and Wales in 1922 5,354 were due to cancer of the pelvic organs, and of these 4,228 were cases of cancer of the uterus. This figure was exceeded only by the 4,826 cases of cancer of the breast. In Scotland in 1923, out of a total of 3,604 deaths from cancer in females, 489 were cases of cancer of the uterus. This figure was exceeded by those for cancer of the stomach 729, cancer of the intestine 595, and cancer of the breast 540. The totals for comparison are, of course, very different, but it is striking that in the Scottish statistics cancer of the uterus comes fourth, and in the English statistics second in order of frequency. I do not venture on any explanation. Cancer of the uterus accounted for 16.5 per cent of all deaths in females from cancer in England, and 13.5 per cent in Scotland in 1923. In America in 1915, out of 47,124 deaths from cancer in females, 11,965 were from cancer of the pelvic organs. It is unnecessary to quote further figures to show the frequency of the disease and its high mortality. Nor need we stress the point brought out by statistics over recent years that cancer generally is apparently increasing in frequency. We are not concerned at present with discussing whether this increase is only apparent or is real. It is enough for our purpose to face the facts as they are, and to try to find means for diminishing the incidence and fatality of the disease.

In attempting to diminish the incidence we must not be discouraged by the fact that we do not yet know the ultimate cause of cancer. There are many diseases, such as malaria, yellow fever, and sleeping sickness, the incidence of which was diminished before their ultimate cause was known, simply by controlling one factor which appeared to play a part in their causation. The nature of all the agencies which have to work together before cancer can develop in the uterus we do not know, but one condition—namely, irritation—is so constant in cancer of the cervix that it must be recognized as one of the etiological factors, and it is a factor which can be controlled.

Cancer of the cervix is ten times as common as cancer of the body of the uterus, and cancer of the cervix is essentially

a disease of the parous woman. Frank's statistics show that 97 per cent of all cancers of the cervix occur in women who have borne children. The number of pregnancies and labours plays a secondary role. The fact that a woman has had one child predisposes her to cancer of the cervix, that predisposition is almost certainly due to injury of the cervix. If that injury is followed by chronic infection and catarrh, as is so frequently the case after deep lacerations, the predisposition is increased. We know that cervical catarrh occurs in nulliparous women as the result of infection, and even in virgins in whom infection can be excluded, and these may be the nulliparae who develop cancer.

Local Irritation

If this factor of local irritation, present in the vast majority of women who develop cancer of the cervix, were more fully recognized and more effective means were adopted to eliminate it, would not the incidence of cancer of the cervix be diminished? That diminution would be brought about, first, by abstention from all procedures which tend to produce deep lacerations, such as forcible dilatation of the cervix in labour and the application of forceps before completion of the first stage, and, secondly, by the thorough treatment and, if necessary, repair of existing lesions. Women should be made to understand that long continued leucorrhoeal discharge indicates a diseased condition and calls for investigation and treatment.

When a woman comes to us complaining of this symptom we must do something more than merely prescribe a vaginal douche. A careful examination should in all cases be made, and the cervix inspected through a speculum. If the laceration is a deep one and the lips of the cervix are everted and catarrhal a repair or amputation should be advised. A repair, when properly carried out, does not prejudice the patient as regards future child-bearing, but, if this be feared, the operation may, in certain cases, be postponed until the child-bearing period is over. The importance of cervical laceration and catarrh, as a cause of disability and possible future trouble in women, was emphasized many years ago by Emmett. In the intervening years its importance has been rather forgotten, and it is only comparatively recently that we in this country are again realizing that these cervical lesions demand proper treatment. The operation is a very simple one and devoid of risk. I believe that its more extensive employment in women at the end of their child-bearing period would result in a diminution in the incidence of cancer. It is extraordinary how women will allow these vaginal discharges to continue over a long period of years without seeking relief therefrom. A similar condition in any other part of the body would lead them to seek advice immediately. In this matter it is obvious that the public requires educating, and the profession also needs to realize more than it does at present the importance of these lesions as a precursor of cancer. Repair of cervical lacerations is one of the most frequent operations which I perform in hospital practice.

Early Diagnosis

While much may be done by this form of prophylaxis, we must look to the early diagnosis of cancer itself for a diminution in the mortality of the disease. In order that these may be obtained two things are necessary: first, the education of the public in the early symptoms and signs of the disease, and, secondly, the instruction of the individual members of our profession to grasp the importance of making a most thorough investigation of any woman seeking advice because of those symptoms and signs. Women must be made to realize that the occurrence of any abnormal bleeding, or the change in the character of any existing leucorrhoeal discharge may be of serious import, and should lead them immediately to seek medical advice. A very large number of women know the import of those symptoms, but abstain from mentioning them because they fear that cancer may be diagnosed. It is therefore important that along with any publicity campaign for the information of women regarding those symptoms, emphasis should be placed on the fact that cancer, if detected early, is a curable disease, that at first it is a purely local condition and in no sense constitutional. If this were more fully realized we should

have coming to us many more early cases which are amenable to treatment.

The number of early cases which we see is very small in proportion to those more advanced. It is usual to divide the cases into "operable" and "inoperable," those being classed as "operable" in which the disease is confined to the cervix or extends only slightly to the vaginal wall, and in which there is no fixation of the uterus or obvious secondary deposits. Many of these cases, however, at operation show extensive involvement of the parametrium and of the pelvic lymphatic glands. When the disease has so extended the chance of cure, either by operation or by radium therapy, is very much diminished. According to this classification we find from the statistics of various hospitals that the number of "operable" cases presenting themselves varies from 40 to 70 per cent. Maitzloff states that in the Johns Hopkins Hospital 52.1 per cent of the cases were operable and these yielded a 26.6 per cent of five-year cures. Craves in Boston found 64 per cent of the cases operable, and these gave a five-year cure of 18.5 per cent. Stoekel gives his operability rate as 70.6 per cent, and in these the percentage of five-year cures was 26.6.

In this country we have not done as much in disseminating a knowledge of the early symptoms of cancer as has been done in America, and especially in France and Germany. That the propaganda in these countries has had good results is shown by the larger number of early cases going to their clinics. Compare the 70.6 per cent operability rate of Stoekel in Germany, the 60 per cent rate of Craves in Boston, the 52.1 per cent rate in Baltimore, and the 27 per cent rate in my clinic in Edinburgh. I believe that much more might be done here by judicious propaganda in the daily press. Public opinion would probably not allow of the general display of posters detailing symptoms, such as we see in Continental cities, but more might be done in other ways. In any such poster or announcement the first thing that should arrest the attention is a statement that cancer is a curable disease. Unless that fact is driven home a large proportion of women with cancer will still delay in seeking advice.

Duration of Symptoms

It is interesting to analyze the extent of the disease in relation to the duration of symptoms. Schmitz finds that, when the irregular vaginal bleeding is of less than three months' duration, the chances are that the case will be one in which the cancer is still confined to the cervix and operable. If the bleeding has been of longer duration, and especially if there is pain, there is almost certainly an extension to the parametrium. The presence of fetid discharge is of less prognostic significance than bleeding or pain. Irregular bleeding between the periods, or after the menopause, is the most constant and significant symptom of cancer—both of the body and of the cervix. Leucorrhoeal discharge, whether fetid or not, is of less importance. Norris and Vogt, in assessing the relative values of these two symptoms from the diagnostic point of view, put hæmorrhage at 90 and discharge at 10 in cancer of the cervix, and hæmorrhage at 75 and discharge at 25 in cancer of the body. Pain, as we all know, is never an early symptom of cancer of the cervix, its presence, practically always, indicates an extension beyond the uterus, and is, therefore, of very serious prognostic significance.

Age Incidence

Another most important aspect of the problem which requires to be put before the public and the profession alike is the age incidence of the disease. Cancer of the cervix most commonly occurs between the ages of 40 and 55. Hevran, in a series of 505 cases, found that one-third of them were under 45, one-third between 46 and 55, and one-third over 56. Norris and Vogt found that 86.9 per cent were 41 years or over. Whilst the disease is uncommon, therefore, at about the time of the menopause, we must remember that it may occur in quite young women. Schmitz found that it occurred before the thirty-sixth year in 11.9 per cent of his cases. I have myself had three patients who were under 30 years of age. Cancer of the body of the uterus, on the other hand,

usually occurs at a later age than cancer of the cervix. In most cases the menopause has been established for some years. The first symptom may be a slight amount of vaginal bleeding or simply a watery discharge which, in the course of time, changes to a blood stained one. Such symptoms in a woman past the menopause should call for immediate investigation. It must also be emphasized that cancer of the body, while commoner in nulliparae than cancer of the cervix, is not essentially a disease of nulliparae. In Norris and Vogt's cases only 26 per cent of all the cases of cancer of the body were nulliparae.

Methods of Investigation

It has long been my teaching to students that the first thing which should cross their mind when a woman of my age comes to them complaining of irregular vaginal bleeding is cancer, and that they must not be satisfied until they have definitely excluded it as a cause. One of the hardest things to teach them is the method of investigating such a case and of establishing a definite diagnosis. After going over the whole matter in the lecture room and at the bedside one often finds that, when confronted with the individual case, they fail to realize that a mere digital examination may be insufficient. There is no credit in diagnosing by vaginal examination an advanced case of cancer of the cervix. What we have to teach them is to be able to recognize the early case, and the ease of early cancer of the body. They must be taught that every woman complaining of abnormal vaginal bleeding is entitled to the most thorough examination. She must never be put off with drugs or douches. If digital examination reveals nothing the uterus must be explored. Many cancers of the cervix begin within the cervical canal and are inaccessible to the examining finger until they are far advanced. Those cases are very deceptive, even in their advanced stages, as the disease extends outwards towards the paracervical tissue and may scarcely reach the external os.

What nature should the further investigation of a case where nothing is palpable per vaginam take? We are now all alive to the risk of disseminating cancer cells by manipulation of a cancerous area, and especially by incising or curetting it. I therefore believe that, if any exploration of the uterus is necessary, and especially if curetting has to be done, the diagnosis should be established one way or the other there and then, and, if cancer is diagnosed and the case is operable, the operation should be proceeded with at the time. In the case of cancer of the body the naked eye appearance of the curettings is usually quite characteristic, in doubtful cases frozen sections should be made. If a piece has been excised from the cervix and immediate diagnosis is impossible the area of excision should be thoroughly euterized.

It is no use educating the public in the importance of early consultation in cases of irregular vaginal bleeding and discharge unless every member of the profession realizes the responsibility placed on him, or her, in advising and carrying out this thorough investigation. It is only by this mutual co-operation that we can hope to get the early case.

Prognosis and Treatment

If we do get the early case what are the chances of permanent cure? Collected statistics from a large number of different operators give a five-year cure in 25 per cent as the result of radical operation. Many of these cases were, of course, border line ones, for we are often deceived as to the extent of the disease until the operation is actually in progress.

When we take selected early cases where the disease was actually confined to the cervix the ultimate results are very much better than 25 per cent of cures, such cases also show a high percentage of cures by radium. I do not think we are yet in a position to be dogmatic about the relative merits of operative and radium treatment in these early cases. Some of those who use radium alone are so enthusiastic about their results that they consider operation inadvisable in any case of cancer of the cervix. Expert operators, on the other hand, are just as positive in the other direction. More time must

chance, and more figures must be available, before we can reach finality on the subject. My own feeling in the matter is that, with a clearly operable case, operation preceded by radium treatment offers the patient the best chance. I am driven to this conclusion by the frequent discovery of definitely cancerous lymphatic glands in early cases. Even with the elaborate modern technique of applying radium on chains passed through the pelvis the chances of eradicating these cancerous nodes are greater by operation.

In the border-line and in the advanced cases, radium treatment is the only one which holds out any hope. By it the local disease is checked, and often completely eradicated, with a disappearance of the vaginal discharge, and very often a marked improvement in the general condition of the patient. In a large number life is very definitely prolonged, and in some an absolute cure is effected. Thus Heyman, in a series of 505 cases in the Radium Institute at Stockholm had 20.29 per cent of five-year cures. In the operable and border-line cases the percentage of five-year cures was 40.5. Schmitz in 105 cases had 14.5 per cent of five-year cures. Bailey and Healy, in 85 cases of recurrent carcinoma, had 8 per cent of their patients well after five years. These figures are very impressive, but such results can only be obtained by a very carefully applied technique. The technique of radium treatment is rapidly being improved and elaborated, so that it has become a very specialized procedure.

In judging of the relative merits of operation and radium therapy we must bear this in mind and against the results of our expert operators place only the results of our expert radiologists. Only by observing such conditions can we hope to arrive at a definite conclusion. Cancer of the body of the uterus shows a distinctly higher percentage of cures by operation than does cancer of the cervix. Norris and Vogt in 115 cases found a three-year cure in 44 per cent. At the present time it would seem that operation offers a better chance than radium treatment in such cases.

But whatever the disease, and whatever the method of treatment employed, the chances of cure are in inverse proportion to the duration of symptoms. The pressing problem is, therefore, to get the cases early, and that can only be accomplished by a more widespread educational propaganda among the people. Is it possible to carry on such a propaganda without unduly alarming the women of the country, and without the risk of creating hypochondriacs? I think that it should be possible. Every effort to remove the supposed mystery of medicine ought to be encouraged. A knowledge of a little elementary anatomy is a good thing for the lady, for with a knowledge of anatomy there comes very quickly some understanding of pathology, and with that there is, undoubtedly, a tendency to discuss symptoms more freely than is otherwise the case. Ten years' work among women on the other side of the Atlantic has convinced me that more good than harm results from such knowledge. The women there have less hesitancy in consulting their medical advisers, and they have less fear of surgical operations than the women of this country. It is sometimes thought by us that our transatlantic cousins and Canadian sisters know too much, and speak too freely about their internal arrangements. With that criticism I am not in agreement so long as such knowledge keeps them alive to the early danger signals of disease.

Surgeon to Middlesex Hospital, etc.

THE SURGICAL TREATMENT OF MALIGNANT DISEASE OF THE PELVIC ORGANS

I WELCOME this opportunity of speaking on the operative treatment of carcinoma of the uterus because I have no doubt at all that, down to the present time, it remains the treatment of election for the majority of the cases. I do not propose, in the short time at my disposal to quote the views of others, but to show from my own experience and results what surgery can achieve.

CARCINOMA OF THE CERVIX

Preliminary Considerations

Dealing first with carcinoma of the cervix, I would remind you that here, as in every other variety of carcinoma, the growth extends itself in two ways—tissue infiltration and lymphatic permeation. The first is a gradual crowding out of the normal tissues around the periphery of the growth. It is so slow a process that, even in persons dead of the disease, the primary mass of cancer cells is, relative to the individual it has killed, quite small. It is so defined a process that, were it the only method of extension, it would suffice, in order to obtain a cure, to excise the cell mass by an incision just outside its microscopic growing edge. Lymphatic permeation, on the other hand, is much faster—many inches between the primary cell mass and a lymphatic gland may be spanned in a few weeks, moreover, it is only occurring along certain well defined lymphatic lines, which, in the case of the cervix, fortunately are fewer in number than in any other place-variety of carcinoma. Commonly, indeed, there are but two—one, the most important, straight outwards in the upper part of the crural ligaments and under the meter to the obturator and external iliac glands, and the other downwards in the vaginal wall. The line of rational operative excision must therefore be planned so that, whilst at all points it keeps outside the margin of growth by filtration, it is extended in the regions of lymphatic permeation as far outwards as the anatomy of the parts and the endurance of the patient will permit.

Wertheim's Operation

The operation which fulfils these requirements we owe to the Viennese gynaecologist Wertheim, who, in the face of bitter opposition, had the courage to persist in its performance until its worth was manifest. I do not think that Wertheim's services to humanity have been properly recognized, so I will take this opportunity of reminding you that in this country twenty-five years ago not more than ten out of every hundred cases of carcinoma of the cervix were able to be treated by removal of the primary growth, and of these ten not more than one was alive five years afterwards. To-day, in England alone, there must be hundreds of women who, thanks to Wertheim, have escaped a peculiarly cruel form of death.

From 1907 to the present day I have performed Wertheim's operation about three hundred times, but since no figures bearing on results are of any value unless founded on the basis of five years' freedom from recurrence, I shall deal with the first 192 cases of the series, the 192nd of which was operated upon in July, 1920.

Operability Rate

But before giving you the figures I must explain what these 192 cases stand for. This brings me to the question of operability rate—that is to say, the ratio borne by the number of cases operated upon to the total number of cases seen in the same period. Without knowing this it is impossible properly to appraise a surgeon's results, since it is obvious that he who cautiously selects for operation only those cases which appear early and easy will, on superficial showing, have much better results than he who attempts to remove the growth in every case in which there is the smallest possibility of doing so.

The operability rate of an institution or individual clinic is estimated by comparing the total number of patients with carcinoma of the cervix presenting themselves at the particular hospital or clinic with the total number of radical operations performed over the same period. Thus, during the years 1923-24, 104 cases of carcinoma of the cervix presented themselves at Chelsea Hospital for Women, out of which 57 were radically operated upon—that is, an operability rate of just on 55 per cent. It has been objected that even in an instance like this, the cases had, to an extent, been previously selected, because certain patients, on account of age, hopeless advancement of the growth, or extreme poverty or neglect, are doubtless sent direct to their local workhouse infirmary and never come to the hospital at all, but since this objection applies equally to all average hospitals, the value of the operability rate as a basis of comparison is unaffected. It is otherwise, of course,

mention occurs chiefly along the lymphatics which accompany the ovarian vessels in the ovarian pelvic ligaments and eventually reaches the upper aortic glands. But much more important than this is the direct infiltration of the uterine wall, which presently penetrating the peritoneum, is followed by multiple peritoneal metastases. This is the usual mode of death in carcinoma of the corpus. The disease, as you know, has a narrower age limit than that in the cervix, occurring chiefly in the first fifteen years during and succeeding the menopause, before which event it is quite rare.

In a discussion on its surgical treatment the problem of diagnosing the disease must be given an important place, because, unlike cervical carcinoma, in which in most cases a correct diagnosis is easily made by rectal digital examination, in corporeal carcinoma to effect the diagnosis alone usually requires an operation. The earliest sign is bleeding, at first irregular and scanty but later on continuous and often free. When bleeding comes on after the menopause its possible significance is less likely to be overlooked or underestimated than when it comes on during the "change." A mistake then is much more likely to be made, not only by the patient but also by her medical man. It must further be remembered that bleeding, although the first sign, may not appear until a late stage of the disease, and in some cases is absent even where the growth has advanced to the stage of massive peritoneal secondaries. In some instances a profuse watery discharge takes the place of the more usual bleeding, and again the medical man may overlook the possibility behind it.

The size of the uterus, as estimated by vaginal examination, is of no help in diagnosis, for though some forms of corporeal carcinoma do enlarge the uterus considerably, yet in at least three cases out of five the organ is no larger than would be normal for an elderly woman and if enlargement is detected it is often difficult to distinguish it from that due to old fibroids, with which carcinoma is often associated. In many of the patients the vagina is shrunk and the vaginal cervix is atrophied, and when in addition a patient is stout as many of them are, ordinary examination reveals little or nothing except perhaps some blood on the finger-tip. It is necessary, therefore, to explore the interior of the uterus under an anaesthetic but this is by no means infallible, for even with a quite fairly advanced growth it may be impossible to scrape out anything apparently worth microscoping. It is most important to realize this. There is a further difficulty—namely, that in many carcinomas of the corpus the stroma of the malignant gland tubules is so similar to that of innocent endometrial hypertrophy that distinction is difficult when the material the pathologist has to work upon amounts to no more than a few tiny fragments.

In making up his mind in a doubtful case the surgeon, therefore, should take its whole aspect into consideration, besides the facts obviously elicited by examination. Bleeding after the menopause can occur from causes other than carcinoma, but it is always a menacing sign, and the likelihood of error should always be on the side of interpretation too grave rather than one too optimistic.

The operation I perform is a free total hysterectomy, taking out with the uterus the vaginal vault and both appendages and dividing the ovarian pelvic ligaments at the point where they take off from the pelvic brim, unless I have reason to believe that perimetrium has already extended along them, when I follow up the ovarian vessels under the posterior peritoneal peritoneum to near their origins from the great vessels and divide them there. I do not perform Wertheim's operation for carcinoma of the corpus except in special instances, holding that the very slight gain which it affords in the matter of freedom from recurrence is more than balanced by its increased operative risk. The exceptions are those occasional cases in which the whole uterus—cervix included—is carcinomatous and also those in which a secondary growth is present in the vagina. Such secondary growths occur occasionally also in carcinoma of the cervix, and unless situated very low down can be dealt with by removing the whole vagina from above, as I have described when dealing with Wertheim's operation. Where, however, the nodule

is right down at the outlet it is necessary to perform a combined abdomino-vaginal operation, or what I call a "super-Wertheim." My method of doing this is first to open the abdomen, and, after having ligatured both internal iliac arteries, proceed as with an ordinary Wertheim to the stage of complete separation of the uterus and upper vagina from all adjacent structures. I then temporarily close the abdomen and, placing the patient in the lithotomy position, dissect free the lower end of the vagina, together with a part or all of the vulva, if that be necessary. I make this the second stage of the operation, because the previous ligation of both the internal iliac arteries markedly reduces the amount of blood lost during this dissection. I then close the lower end of the freed vagina by suture and, replacing the patient in the Trendelenburg position, remove the temporary sutures closing the abdominal wound. I then separate the vagina from above until it is entirely free, so that it, together with the uterus and its attached structures, can be lifted out through the abdominal incision. The regional glands are then removed, a full peritoneal floor is formed in the usual way, and the abdominal wound is closed.

I have performed this operation on a good many occasions, and although it is more severe than the ordinary Wertheim's operation, my immediate results have been fairly satisfactory. As regards the remote results, however, I cannot say this, most of the patients having died of recurrence sooner or later.

I have not followed up the patients on whom I have operated for carcinoma of the body of the uterus with the same thoroughness as I have in the case of those with cervical disease, but I have no doubt that the results of the operation are at least as good. The primary mortality of the operation at Chelsea Hospital for Women, from January, 1905 to the present time is 8 per cent. This is the result of the work of many operators. It is higher, perhaps, than one would have expected, but it must be remembered that many of these patients do not present themselves to the surgeon until the disease is very advanced and the discharge exceedingly foul and septic.

As regards recurrence my own experience is that at least 50 per cent of the patients recovering from the operation are free from recurrence five years afterward. Unfortunately, I cannot base this estimate on accurate statistics, but it accords with the figures of Wertheim, Mayer, and Winter, and I think it would be agreed to by all surgeons who have much experience of hysterectomy for carcinoma of the corpus. The most favourable group of cases are those in which the malignant growth is associated with fibroids, because the much increased size of the uterus considerably extends the area over which the malignant cells may extend without exceeding the limits of operative extirpation. This particularly applies to direct spread to the peritoneum.

The operation for carcinoma of the corpus is, therefore, upon the whole a far less difficult and severe procedure than in the case of carcinoma of the cervix, but though this is generally true it is often otherwise. I know of no exercise more fatiguing to the surgeon than abdominal extirpation of a small carcinoma of the uterus when the patient is exceedingly fat and the abdominal wall is rigid. The latter handicap is far more frequently present in corporeal disease than in cervical disease, because so many of the patients have not borne children. I shall never forget performing the operation on a patient of this sort who weighed 22 stone.

This leads me to the subject of vaginal extirpation of the uterus as an alternative to the abdominal operation in some of these cases. There are some cases in which I think it is preferable, but not many, because the combination of great fatness with rigidity of the abdominal wall, which makes the abdominal operation so difficult, is largely limited to patients who have had no children, and in them the vaginal route is equally made difficult by the narrow calibre of that passage. I have performed Schauta's operation (hystero-vaginectomy) both for carcinoma of the cervix and carcinoma of the corpus but I hold that in the majority of cases, it is much inferior to the abdominal operation.

III—S J CAMERON, M B, Ch B, F R F P S, Obstetrical Surgeon and Gynaecologist Glasgow Maternity and Women's Hospital

MALIGNANT DISEASE OF THE OVARIES AND FALLOPIAN TUBES

Those of you who are engaged in gynecological work will appreciate my difficulty in doing justice to the conditions under consideration, for apart from the comparative rarity of malignant disease in the tubes, little information is to be gleaned from the somewhat scanty literature on the subject.

After due reflection I decided to limit my contribution to cancerous and sarcomatous disease of the ovaries and cancer of the Fallopian tubes. Doubtless some of you may regret that I have not included such diseases as chorion-epithelioma, and debited as to whether peritoneal metastases of the ovaries arise from the interstitial cells or not. My excuse is that such considerations seemed to me more appropriate to the special meetings of a pathological or gynecological society, and that if I succeeded in placing before the members of this Association certain facts which would prove helpful to them in the practice of their profession a more useful object would be achieved.

Malignant Disease of the Ovaries

Despite the last statement, I must refer for a moment to the Krukenberg tumour, which is, as you know, a malignant tumour of the ovary. As a rule both ovaries are involved and their shape is retained. This tumour is characterized by globules in the cells which take up the red stain with mucicarmine. Seldom (but still occasionally) the cells make an attempt to form tubules or even small cysts containing intracystic growths. My impression is that the tumour is almost invariably secondary to cancer of the stomach, and in all probability the cells pass to the ovary by way of the lymphatics as peritoneal deposits may be absent, a circumstance one would not expect if the cells were shed into the abdominal cavity. Cells evidently of a sarcomatous nature may be intermingled with the cancerous elements, and it has been suggested that the simultaneous proliferation of epithelial and connective tissue cells may be due to a common cause. In this connection it will be remembered that laboratory workers have demonstrated that transplantable cancer may eventually become transplantable due to stimulation by the cancer cells, but, on the other hand, Krukenberg believed that the tumour was an ovarian sarcoma in which a carcinomatous appearance resulted from alteration within the cells.

Turning from this subject to that of the commoner forms of malignant disease of the ovary, I would impress on you the ease with which the real nature of a cystic ovarian tumour may escape detection. This fact was brought prominently to my notice many years ago when one of my patients from whom I had excised what appeared to be an ordinary multilocular ovarian cyst returned a few months later with a malignant abdominal tumour. A portion of the cyst which had been preserved was subjected to microscopic examination, and the malignant nature of the tumour was revealed. Since a naked eye examination may fail to detect malignancy, it is advisable that every ovarian cyst should be histologically examined. As a rule ovarian tumours always give with suspicion a case in which whose general health has been deteriorating for a few months prior to examination. The diagnosis of malignancy can be made with certainty if free fluid is contained in the peritoneal cavity, and if a sensation of crinkling upon the abdominal wall is detected. The diagnosis of malignancy can be detected only when the disease is advanced, and it seems probable as a result of Fyfe's investigations in connection with the chemical diagnosis of cancer that an early and less crude method of diagnosis will be procurable.

In this communication I present to you the results of my inquiry into 94 hitherto unpublished cases of malignant disease of the ovaries. It is regrettable that in the 83 cases of ovarian cancer I could obtain definite proof in only 31 instances that the disease was secondary to a cancerous

tumour elsewhere. As primary cancer of the ovary is rarer than the secondary variety, I suspect that the size of the ovarian growths frequently dwarfed the primary nodule in the surgical picture, as large ovarian neoplasms of secondary origin by no means predicate a primary tumour of corresponding size. Apparently the ovary provides an exceptionally favourable soil for the growth of cancerous seedlings, as masses of similar proportions are foreign to the peritoneum, which is evidently able to offer greater resistance to the invading cells. It is often stated that a secondary deposit in the ovary reproduces so faithfully the characteristics of the parent tumour that the site of the primary growth can be located by microscopical examination of the secondary neoplasm. That there may be exceptions to this rule is evidenced by the two sections which I show you. The first was taken from the tissue of a primary cancer of the sigmoid, while the second was prepared from an ovarian deposit in the same case. It will be seen that the two sections present different appearances, and the conclusion is that site influences to some extent cellular type and arrangement in the daughter tumour. This is well exemplified in the two slides which illustrate secondary growths in heart and brain from a case of cancer of the liver. Note the papillomatous appearance of the cerebral neoplasm and the scirrhous type of the cardiac tumour. No one would ever suspect that these growths had a common parent. These slides were given me by Dr Cipel.

All the cases recorded in this communication occurred either in the gynaecological department with which I am associated at the Western Infirmary, Glasgow, or at the Cancer Hospital, Glasgow, and I am indebted to Miss Mackenzie, who has diligently searched the journals of these institutions for clinical and pathological notes of the cases. The investigation showed, as was expected, that cancer of the ovary occurred much more frequently than sarcoma, the relative percentages being 88 and 12. Of the 31 definitely secondary examples of cancer of the ovary the primary nodule was situated somewhere in the gastro-intestinal system in 12 instances, in the uterus in 9, in the breast 8, in the bladder and kidney 1, and in the kidney alone 1.

It seems to me, however, that the cases in this series which were secondary to malignant disease of the uterus form an abnormally high percentage. In analysing details of the available material I arranged the cases according to age into five-yearly groups, the first including patients between the ages of 19 and 25 and the last between 69 and 75. It occurred to me that a certain amount of interest was to be derived from the records of each group by noting such features of the disease as pain before operation, uterine haemorrhage, ascites, distribution, operability, and the expectation of life after removal of the tumours. The results of this investigation may be summarized thus:

Age 19 to 25—Two cases were met with the average age incidence being 21. Pain was present in one instance before the patient came under observation. Ascites and uterine bleeding were absent in both the disease was bilateral and in one the tumours were irreparable. A note sent to the patient who was subjected to operation failed to elicit a reply.

Age 24 to 30—Five cases occurred between these ages the average being 26. Pain was complained of by all these patients and all but ascites occurred in 60 per cent of the cases. In one instance the patient had been ailing for one and a half years before she consulted a doctor and the average duration in the other four cases was three months. In three instances the disease was unilateral and removal was accomplished in these cases but the average duration of life afterwards was only three months.

Age 29 to 35—There are only two cases in this group the average age being 33. Discomfort existed in both cases before the patients were treated and the general health had been in an unsatisfactory state for an average of seven months. Bleeding from the uterus was observed in one case, and ascites in the other. The disease was bilateral and so extensive in the affected ovary did not prolong life to any extent as the patient died two months later.

Age 34 to 40—Eight cases are in this section, the average age being 36. Again pain proved a common symptom and was noted in 75 per cent of the cases. Haemorrhage was found in 62 per cent and in 50 per cent the patients had been ailing for six months before they came under medical supervision. Bilateral tumours occurred in 37 per cent and in 42 per cent removal was accomplished. One patient with an adenocarcinomatous tumour lived for four and a half years afterwards, death then resulting

from recurrence of the disease. Of the other traceable patients subjected to operation 25 per cent lived for seven months.

Age 39 to 45—Eight cases also occurred between these ages the average being 41 years. In 75 per cent of the cases pain was noted but there is no mention of uterine haemorrhage in any of the clinical histories. Ascites was evident in 50 per cent of the cases and 62 per cent had been in poor health for five months before advice was sought. The disease was unilateral in 75 per cent but in only 25 per cent could a radical operation be performed. One patient was in a satisfactory state of health fourteen months after operation but the other died in ten months time.

Age 45 to 50—More cases were met with in this division than in any other and of the seventeen patients the average age incidence was 47. Pain was noted in 70 per cent, haemorrhage in 17 per cent and ascites in 41 per cent. In 70 per cent of the patients their health had been deteriorating for an average of five months before a doctor was consulted. As regards the distribution of the disease it was bilateral in 47 per cent and extirpation was only possible in three instances. One patient who had her enucleated ovaries excised by me nine years ago consulted me recently owing to recurrence of the disease in nodular form within the abdomen. Another patient survived for three years but the third case only lived for thirty four days.

Age 50 to 55—Fourteen cases comprise this group the average age being 51. Bleeding existed in 21 per cent of the cases and ascites in 42. An unsatisfactory state of health was present in 42 per cent of the patients for an average period of twenty months before they reported sick but in a similar percentage of cases the average duration of ill health was only four months. In the remaining case information regarding this point was not obtainable. In one half of the cases both ovaries were implicated and in 43 per cent the tumours could not be extirpated. When the records of the patients who had undergone operation were examined it was found that 14 per cent remained in good health after an interval of four years, 21 per cent lived for eight months and 7 per cent for three months. The remainder either died in hospital soon after operation or failed to reply to the note of inquiry.

Age 55 to 60—In this section there are twelve patients the average age incidence being 57. Life was rendered miserable by pain in 58 per cent of the cases, uterine haemorrhage was observed in 25 per cent and ascites in 33 per cent. No less than 54 per cent had been in declining health for an average of eighteen months and 27 per cent for five months. The distribution was unilateral in 50 per cent and in a similar percentage of cases excision of one or both ovaries was performed and of the patients who survived only 14 per cent lived for sixteen months while 43 per cent succumbed in from five to seven months. The remaining cases could not be traced.

Age 60 to 65—The average age incidence of the seven patients in this division was found to be 62 and pain was a symptom in 43 per cent of the cases. Bleeding was noted in 28 per cent of the patients and free fluid was detected in the peritoneal cavity in 43 per cent. The average period of ill health prior to medical supervision was five months. Unilateral tumours were found in 57 per cent and the growths proved inoperable in a corresponding percentage of cases. In 43 per cent of the traceable cases which had been surgically treated the average duration of life was six months but one victim of an encephaloid cancer lived for fifteen months.

Age 65 to 70—Five cases were met with and the average age incidence was 66. None had uterine haemorrhage but in 60 per cent ascites existed. All the patients had been in declining health and that for an average period of seven months in every instance pain was an accompanying symptom. A single ovary was involved in 20 per cent of the cases and in no less than 60 per cent removal proved impossible. One patient is leading a normal existence six months after operation but in another instance a fatal termination was reached in three weeks. Information could not be obtained regarding the fate of the other three patients.

Age 70 to 75—There were only two patients in this group and in one instance pain was a symptom. Neither patient had uterine haemorrhage but ascites was noted in one instance. Failing general health was observed in both instances for about nine months before the cases were examined. A single ovary was involved in each instance but only one patient was in an operable state and she died five weeks after removal of the tumour. In one case the age was not stated.

From a perusal of these notes the following tentative conclusions may be arrived at.

Age Incidence—It was found that 48 per cent of the patients were aged between 44 and 65 years, 30 per cent between 44 and 55 years, and 18 per cent between 54 and 65 years. Of the five-year periods the 44-50 group contained the greatest number of cases, but in illustration of the widespread distribution of the disease among patients of all ages it should be noted that the number of patients below 45 years of age almost equalled the number above 55 years.

Pain—Owing to the relatively small numbers in the various groups it is not desirable to state the results in exact figures. It appears however, that this symptom was present in 50 to 75 per cent of the cases, but that there was no relationship to the patient's age.

Uterine Haemorrhage—In the age-group 34-40 this symptom was noted in approximately 60 per cent of cases. Among the patients from 39 to 65 years it occurred in about

25 per cent of cases, while it did not occur in any patient older than this. The high incidence of bleeding in the 34-40 years group may be due to endocrine disturbance, and may not be directly associated with any special feature of malignant ovarian disease at this age period. The absence of bleeding in cases over 65 may be due to extreme uterine atrophy.

Ascites was noted in 40 to 60 per cent of cases in the several groups but appeared quite unassociated with age.

Period of Ill Health—Among the patients below 50 years of age the duration of ill health before examination varied from three to six months. Many between 49 and 60 years of age did not have a longer period of ill health than this, but, on the other hand, in about 50 per cent the initial illness extended over a period of twelve, eighteen, or even twenty months. In patients over 65 years of age the average duration was about seven to nine months. It may be that in the older patients the tendency to slower growth affords an explanation of this while the relatively shorter period in the extremely old people may be accounted for by their feebleness.

Unilateral tumours occurred in about 60 per cent of cases—this occurrence could not be correlated with age.

Operability—In the various groups this ranged from 30 to 45 per cent and was not associated with age the greater malignancy in the young apparently compensating the greater debility in the aged.

Expectation of Life—It appears that the very old and the very young patients succumb slightly more quickly after operation than the middle aged subjects but on the whole the average is about five to six months. The most favourable result was obtained in one patient of the age of 44 to 50 years group, who lived for nine years after operation at the end of which period she was readmitted with an inoperable recurrence.

At the outset of this investigation I was not prepared to find that so many patients had been induced to seek surgical aid owing to pain and haemorrhage. I had not associated either symptom with this disease, but this inquiry demonstrated that they are not infrequently accompanied by ascites and failing health of a few months' duration. Nevertheless we must not forget that in some instances the only two complaints are general weakness which is associated with progressive enlargement of the abdomen. Scrutiny of the operative results also emphasizes two distressing features of this disease—namely the large percentage of inoperable cases and the short tenure of life after excision of the growths. In these respects cancer of the ovaries compares unfavourably with cancer of the cervix, but we should remember that about twenty five years ago the surgical aspect of the latter disease was extremely discouraging. In dealing with malignant disease of the ovaries are we to practise the operation of ovariectomy, or are we to employ a more extensive operation? Success has attended radical operations in combating malignant disease in other parts of the body, such as the uterus and breast, where, previously, restricted procedures had failed, and it seems to me that in the present state of our knowledge relief is most likely to be obtained by similar measures. In our present inability to make an early diagnosis surgical treatment is frankly disappointing, and future success may depend on biochemical diagnosis, or on the use of serums, or on the perfecting of a new technique. Within the last few days the attention of the entire medical world has been attracted by the publication of the investigations of Gye and Bernard. This interesting research may result in the discovery of a method of immunization which will protect the individual against cancer and other diseases, or relieve him should he fall a victim to one of these disorders. All interested in this matter should study the contributions of these authors, but it is evident that the cancer problem remains unsolved.

Sarcoma of the Ovary

The patients involved were of widely varying ages, only two falling within the same five-yearly group. Eleven cases of sarcoma of the ovary were noted, and in seven the disease was primary. Of the primary cases the youngest was aged 22 and the oldest 52, the average age of 41 being considerably younger than that of patients

afflicted with cancer of this gland. Four of the patients had borne children, and the average duration of failing health before coming under observation was six weeks.

In every instance pain was a symptom, while uterine bleeding was present in three cases and ascites in four. Amenorrhoea was noted in two patients. Unilateral distribution was universal, and in four instances the diseased ovary was extirpated. The results of operation were generally disappointing with one exception, where a patient remained free from recurrence for twelve years, when secondary growths appeared in the uterus, bladder, and intestine after this long interval.

It should be remembered that some forms of fibrosarcoma of the ovary are slow growing and do not recur readily after removal. Favourable reports appear from time to time in connection with the treatment of sarcomatous tumours by x-rays, and while I do not depreciate the temporary comfort and improvement obtainable from the use of radium and x-rays in certain gynaecological lesions, I would utter a word of caution in connection with this matter. On two occasions during my surgical career I have treated and abandoned an operation in the belief that I was dealing with an irreducible ovarian tumour of a malignant nature. After the attempted operation one patient was treated by deep x-ray therapy, while the other was not, and therefore furnished an excellent control. Both patients still enjoy a fair measure of health and the tumours have not increased in size. It is certain that in the untreated case and probably in the treated one an error in diagnosis had been made. Both tumours were probably innocent, and but for the untoward control I should have credited deep x-ray therapy with arresting permanently the progress of a malignant growth as four years have elapsed since she was treated.

In two out of the four cases of secondary ovarian sarcoma I find that the primary growth was situated in the mediastinum. The remaining examples occurred in patients so far removed in age as 22 and 64. In the younger woman a wart was noticed on the vulva at the age of 15, and when she was 20 a rapid increase in size was observed during the third week of the puerperium. About three weeks later one leg and groin were greatly thickened, and in a few weeks' time free fluid distended the abdomen. At the post-mortem examination secondary deposits were found throughout the abdominal cavity, one omental mass actually weighing 7 lb. On microscopic examination it was found to be a spindle-celled sarcoma with connective tissue of embryonic type which had in almost myxomatous appearance. In the older patient the disease also took an acute form, death resulting ten weeks from the onset of symptoms. The primary nodule was situated in the neurofibroma and the patient complained of tingling neuralgia. Secondary deposits were also found in the uterus.

Cancer of the Fallopian Tube

This disease is so seldom met with that some gynaecologists have never operated on a case. Even with the opportunity which I have had during twenty years of practicing a large number of women suffering from pelvic disorders I have only encountered two cases, and in one instance the nature of the lesion would have escaped detection if the patient had been less courageous and determined. The incidents associated with the treatment of this case have served as a salutary lesson to me in demonstrating that our measures are often concealed and that inability to accomplish an objective may eventually prove a fortunate circumstance. To amplify these statements let me give you a brief history of the case. The patient was a nullipara, aged 62 who complained of a copious watery discharge which caused vaginal and vulvar irritation. Attempts at a diagnostic cure ting were rendered futile by the extreme narrowness of the vagina, which was also irregularly constricted by stout bands of cicatricial tissue. As this was the only occasion in my career where I had been unable to perform this simple operation, it was in a spirit of humility that I confessed my failure to the patient. By persistent interrogation she elicited from me the information that the presence or absence of cancer of the uterine body in her case could

be determined by hysterectomy alone. She insisted then that the operation should be performed without delay, and events justified her decision, as on opening her abdomen I found that she had a primary cancer of the right Fallopian tube, but it was so slightly thickened that it is questionable if its presence would have been detected readily on rectoabdominal examination. The disease had extended on to the outer surface of the uterine body, and I had succeeded in enucleating the uterus. I would have assumed the patient that she was not the victim of a cancerous growth, as I would have failed to extract material for pathological examination. At operation, the only evidences of inflammation were numerous peritubal adhesions, which may have been produced by the neoplasm. Many observers believe that salpingitis precedes tubal cancer, and it is interesting to note that on one occasion I removed a pus-laden tube which contained a cancer of columnar type. Nevertheless, I presume that few now would assert that salpingitis is an essential precursor of tubal carcinoma.

The second specimen of tubal carcinoma was removed from a nulliparous patient, and its presence was unsuspected until the abdomen was opened for the removal of large fibromyomatous tumours, which were causing profuse uterine haemorrhage. In this instance also the right tube was involved, and showed considerable elongation. A solid tumour, about the size of a turkey's egg, occupied the ampullary portion. I believe that this tube had been distended with fluid prior to the development of the cancerous growth. The macroscopical and microscopic appearances were those generally found in association with hydrosalpinx. Thus the tube resembled a retort in shape in undulation and a kink occurred in the wall between the neoplasm and the margin of the uterus, while a normal ovary lay in the concavity below the tubal curve. Although the ostium was sealed adhesions were absent in the area where the tubal wall was unattached to the surface of the tumour. Microscopic examination demonstrated that the attenuated tissues of the wall were not invaded by cancerous elements. As hydrosalpinx in some instances may result from inflammation, it is possible that in this case salpingitis predisposed to malignant disease. It is stated by some observers that the intermediate straggle of the growth can easily be recognized on microscopic examination. On searching the literature of this subject I find that when cancer appears in the tube it usually takes a papillary form. The disease in this second specimen was limited to the tube, and a healthy section existed between the neoplasm and the uterine margin. Although in both these specimens the disease was unilateral and located in the right tube, it appears that the left tube is as liable to be implicated as the right and in about one-third of the recorded cases the disease was bilateral. Apparently, the most prominent symptom of primary cancer of the Fallopian tube is the occurrence of a copious discharge which is usually clear in colour, but may be stained with blood. Women over the menopause are most likely to be affected and nulliparae are as liable to the disease as multiparae. It would therefore appear that the occurrence of a clear, watery discharge in an elderly patient should always arouse the suspicion that cancerous or papillomatous disease of the tube exists if the cervix and body are found to be normal. Careful examination of the fornices usually reveals the existence of a pelvic tumour, but it is curious how seldom ascites is present. This circumstance is probably to be attributed to early closure of the tubal ostium, which thus causes the fluid exuding from the neoplasm to pass into the uterus instead of the peritoneal cavity. Ascites seems to occur only in cases where the peritoneum is the site of metastatic deposits. Pain was not present in either of my cases, but I find that it occurred in the majority of the cases recorded by Dorn to whom we are indebted for valuable information on this subject. Cancer originating in the Fallopian tube may appear secondarily in an adjacent cyst of the ovary and it is worthy of note that primary cancer of the ovary seldom spreads to the tube. But Glendinning has demonstrated that in cancer of the ovary cancer cells may pass through the ostium of the tube and become implanted

on the tubal lining. At various points these wandering cells penetrate the epithelium and enter the lymphatics of the tubal wall. From here they pass into the mesosalpinx. In Glendinning's sections unattached cancer cells can be seen in the tubal lumen, and at other parts penetration of the subepithelial tissues by the cancerous elements can be observed. Discrete cancerous nodules are most numerous towards the ampullary extremity of the tube. Naked-eye examination may fail to reveal involvement of the tube in cases of ovarian cancer, and this was the case in the specimen from which the section shown in this lantern slide was procured. On operating I knew that I was dealing with a malignant papillary cyst, but I did not realize that the apparently normal tube contained metastatic deposits until I prepared microscopical sections. The little papillary budlet which you see is situated in the tubal wall, and it may have reached this point by leaving the ovary in the efferent lymphatics and by next pressing up into the lymphatics which drain the tube. At any rate I was unable to discover penetration of the tubal lining by wandering cancer cells.

GENERAL DISCUSSION

The PRESIDENT stated that in view of the steady increase in the deaths from cancer during the last fifty years, the Section could not have chosen a more important subject for discussion. During the last twenty years the mortality rate from cancer had risen from 800 to 1,250 per million, whereas in the case of other diseases the mortality rate was diminishing.

Mr. H. J. DREW SMYTHE (Bristol) heartily agreed with Mr. Victor Bonney in the necessity for the most radical operation for carcinoma of the cervix, and was interested to hear that he removed the whole of the vagina. He had been in the habit of only removing half, and in one of his cases the growth recurred in the other half. During the year 1923 he had performed Wertheim's operation seven times, two of these patients died as a result of the operation, and in two cases there was recurrence, one in the vagina and the other in the pelvis, the other three patients had had no recurrence so far, and he hoped that they would not in the future. In one case he had to dissect the base of the bladder, leaving the mucous membrane intact, the patient, however, died from the effects of the operation. He agreed with Mr. Bonney that the only sure way of telling whether a case was operable or not was to open the abdomen. In one of his cases he was able to perform Wertheim's operation, though on ordinary examination he thought it hopeless, and that patient was still alive and free from recurrence. Last year he treated with post-operative irradiation two patients that were in hospital at the same time. In one case the growth recurred in the pelvic wall within six months and attained extreme rapidity, the other, however, was free from recurrence fourteen months afterwards. He had not tried a case since those two. With reference to preliminary irradiation to reduce the size of the growth or to render the case operable, he said that the fibrosis resulting made operation extremely difficult. He would plead that day for the earlier diagnosis of carcinoma of the uterus, and more especially for the medical treatment of the precarcinomatous cervix. There were numbers of cases with a history of slight intermenstrual haemorrhage and discharge. The cervix was found lacerated with a large red hypertrophied erosion which bled slightly on examination, but the cervix on palpation was hard though not friable and ulcerated as with a carcinoma. This was a typical precarcinomatous cervix. In his opinion, with this condition in a patient of 40 or more a panhysterectomy should be advised. This might sound too radical an operation, but what else was there to offer? (1) Cruties—these were more likely to accelerate the carcinomatous change. (2) Curettage—this did not remove the epithelium of the deep glands, and it was there the carcinomatous change was recurring. (3) Amputation of the cervix—this left a certain amount of the cervix behind, and though carcinoma in situ was unlikely, yet it was possible. The operation had a definite mortality, and he maintained that a panhysterectomy in selected cases had no greater mortality

than amputation of the cervix. During the year 1924-25 he had performed panhysterectomy for a precarcinomatous cervix, both in private and hospital cases, eighteen times without a death. He was sure that the future of carcinoma of the uterus lay in early recognition and early radical operation rather than in extensive operations with high mortality after the cancer had risen.

Dr. W. C. SWANN (Bristol) said that Mr. Bonney's statistical tables gave most startling information as to the possibilities, both immediate and remote, of the more extensive methods of operating in cases in which the disease was advanced, obviously in the earlier cases the results would be far superior. He mentioned two cases of his own treated by vaginal hysterectomy which were living and well twenty years later. This was not to be taken as proof of anything, except that in a proportion of cases in inadequate operation might produce good results if the case was dealt with sufficiently early. Professor Watson had alluded to education and propaganda. As regards the public this must be done by the family doctor. It must be remembered, however, that while the receptivity of the public for propaganda and education varied enormously in different districts, the family doctor was the person who could best supply it, either indirectly or directly. The capacity for carrying on educative or propaganda work depended on those who, like Professor Watson, were engaged in teaching. While under present conditions it was practically impossible for every student to get the opportunity of examining more than one or two cases of carcinoma, it was possible to see that every student was thoroughly drilled in taking histories of cases until he automatically recorded the instances in which the patient deviated from his own physiological normal. This necessitated a clinical examination in the subject in order that this part of his instruction might be brought before the student in its proper perspective. Mr. Bonney had referred to the extensive operation as one for a specialist, he might have gone further and said that it was an operation for two specialists. Anyone who had watched Mr. Bonney and his colleague, or various Continental operators, performing this operation could hardly fail to be struck with the enormous advantage resulting from both operator and assistant not only being experts, but also accustomed to work together. If, however, the best results were to be obtained the early recognition of the cases was the important factor, and this depended on the systematic instruction of the student.

Dr. SIDNEY FORSDYKE (London) congratulated Mr. Bonney upon the results he had achieved by operation. He questioned whether many surgeons would accept and adopt his arguments in favour of operation upon the advanced cases he described. Mr. Bonney's dexterity was so great and his enthusiasm so infectious that there was just a danger that he might induce lesser craftsmen to tread in his footsteps. His operability rate, mortality, and five-year cures were not, to his knowledge, equalled. It seemed to him that he approached this question from the standpoint of a deft surgeon fascinated by a difficult problem rather than from the patient's angle of vision. The latter wanted two questions answered: (1) What were the risks attached to this operation? (2) If that risk were taken, would cure of the disease result? To answer these questions in advanced cases they must look at Bonney's table of 78 cases with carcinomatous glands, and there it was found that the number of operative deaths and recurrences were equal to 69 per cent, the number of five-year cures was 25 per cent, the chance of a cure was in the ratio of 25 to 69, or 28 to 1 against. The operative mortality was 23 per cent and the five-year cures were 25 per cent, and to answer the patient's question they must say that the chance of a cure was slightly greater than the chance of death from operation. He wondered whether many patients would be found willing to undergo, or many surgeons to undertake, such operative risks, and he also wondered whether such results were not in great part responsible for the concealment by women of symptoms which would lead to an early diagnosis. But these results were better than others published and unpublished.

In his Hunterian Lecture last year he had recorded the results of 50 border-line cases which came under his care. After the Wertheim operation there was in 58 per cent recurrence within a year, in 18 per cent between one and two years, in 18 per cent within three and a half years, and 6 per cent only of the patients remained alive four and a half to six years. Martzloff (Johns Hopkins Hospital) reported that of 120 border-line patients less than 10 per cent were alive a year after operation, and that the mortality rate varied between 25 and 70 per cent, according to the severity of the operation. There was a general consensus of opinion amongst English gynaecologists that the only treatment for early cancer of the cervix was operation, but he was glad to say that he met an increasing number of surgeons who refused to operate upon the advanced case, and refused to accept Bonney's arguments in favour of a high mortality rate. Was it to be wondered at when Radium-Hemmet reported 40.5 per cent operable or border-line cases free for five years and more, and 16.6 operable cases free from symptoms after five years?

With reference to bias to operation, the most essential examination in a doubtful case was cystoscopy, for that was the only means by which involvement of the bladder could be excluded. Frequency of urine was a common complaint in parous women, and that was the only minor symptom present in a woman he had seen with extensive involvement of the trigone and both ureters, bulbous oedema around the mouth of a ureter in the presence of cancer of the anterior lip indicated involvement of the lymphatics, a widespread oedema of the trigone or an obvious tumour meant a growth so extensive that there was no hope of removing it.

Mr Bonney had given them no information about the methods of post-operative irradiation he employed, and therefore it was difficult to assess the value of his criticism. He himself had operated on 20 border-line cases following exposure to radium. In only one case did he find any difficulty owing to the presence of excessive fibrous tissue, and that was a case in which he postponed operation for five weeks. In the remainder he had operated in the third week, between the fourteenth and twenty-first days, and found no greater difficulty than was usual in the Wertheim operation. As to post-operative irradiation, he had been rather elated about using it on traumatized tissue immediately after operation, but he had seen Professor Adler (Vienna) place tubes of radium against the side wall of the pelvis at the end of the operation, he had never had any ill effect from it, and had formed the opinion that it was advantageous.

Mr C. P. CHILDE (Portsmouth) said that nothing less than examination under anaesthesia with smetting and microscopic examination could be sufficient to establish a diagnosis in an early case. He advised this in every case of deviation from the normal in women of cancerous age. The questions of operability, of death from operation, of early recurrence after operation were of secondary importance to that of really early diagnosis. Radium and the x-rays would probably give better results than surgery in advanced cases. In regard to the pre-cancerous cervix, no one could say exactly what that was. He certainly did not advise panhysterectomy for erosions and lacerations. How could they expect to get good results when most of the cases they saw had been having haemorrhage for six months or more? The student must be educated and women must be educated so that if they noticed any deviation from the normal menstrual function they would submit to examination at once. In that way only could earlier diagnosis be made, and it might then be possible to succeed with a far less severe and radical operation which would carry a very much diminished primary operation risk.

Dr H. LEITH MURRAY (Liverpool) issued the importance of the midwife as a factor in the dissemination of knowledge of early symptoms. He had noted with regret the grossly inaccurate replies given by the bulk of candidates to a question on cancer set at the last examination of the Central Midwives Board. Very many women he found, turned for advice to their midwife rather than their doctor

when the symptom was one of bleeding. Very great harm would be done if that midwife's idea of cancer was limited to a picture of wasting disease with foul blood-stained discharge at, or after, the menopause. With regard to radium he had up to the present left the administration wholly in the hands of radiologists. He had like Mr Bonney, experienced intolerable difficulty where radium had been applied before operation, and preferred the difficulties of huge growth to the sclerosis resulting from radiation. On the other hand, he was convinced that radium, applied either by the vagina or rectum at intervals after a radical operation, was of real service. Comparison of his private cases, who all had radiation, with his hospital cases, for whom there was no provision of radium in Liverpool, was definitely in favour of the former.

Colonel V. B. GREEN-ARMYtage (Calcutta) said that though he had had a considerable experience with women of many races, he had never met with a case of cervical carcinoma in a Jewess. He believed that the experience in America was the same.

Dr W. H. HOWAT (Ayrshire), speaking as a general practitioner, said he was glad to hear the former distinguished speakers stress the dangers of the conditions under discussion, both from the point of the specialist and the general practitioner. Education of the student was, in his opinion, of the greatest importance, and he thought he was right in saying that in Edinburgh and Glasgow their training in the direction of early diagnosis was on sound and up-to-date lines. His own experience led him to believe that radical surgical treatment, on the lines so clearly laid down by Mr Bonney, offered the best results from the point of view of the patients and of the family doctors to whom they returned for after-care and treatment. The difficulties in the way of radium treatment for the patient of the working class a long distance away from a centre inclined him to think that operation offered the best hope of early recovery and return to household duties. He agreed that propaganda was necessary amongst the general public but would point out that the patients were shy and did not care to let anyone know of their sufferings until the condition was fairly well advanced, so that the fault did not lie wholly with the general practitioner in not recognizing the condition at an early stage.

Mr MALCOLM DONALDSON (London) protested very strongly against the sweeping statements made by people who had very little experience of radiological methods. It would be far better to content themselves with a statement of facts giving full details of the technique employed. One of the speakers condemned radium on his experience of patients who were treated for only a few hours at intervals of six weeks. Such remarks did a great deal of harm.

Mr R. H. PARAMORE (Rugby) referred to the importance of the prophylaxis of malignant disease of the cervix. Professor Watson had stated that leucorrhoea and split cervix were predisposing causes, an opinion with which most would agree, and had suggested that cervical tears, if not repaired during the child-bearing period because of the likelihood of rupture again at some future labour should at least be dealt with when that period was past. In the speaker's opinion it would be much better to remove than to repair the cervix, but he went further and agreed with Mr Smythe in prophylactic panhysterectomies. In women of 45 or over showing simply irregular uterine bleedings, or in other cases in which the uterus was obviously diseased, as in fibroids, panhysterectomy should be performed, unless indeed the patient were very anæmic or the pulse rate unduly high. Subtotal hysterectomy was too commonly practised. The risk of complete removal was certainly somewhat greater, but the risk was small. He did not agree with Mr Childe's advocacy of a preliminary smetting in suspected cases. It had already been said that that operation favoured dissemination of the cancer cells, and it certainly caused delay in the radical removal. But there were other objections. It entailed two operations and the risk of two anaesthetics, and it prolonged the period during which the patient was under treatment. There were other dangers also. He

had heard of a case in which a woman had been enucleated and the scrapings, with some others, had been sent for microscopic examination and report. The specimens and reports had been mixed, and the patient who had not carcinoma was subjected to Wertheim's operation, fortunately she recovered.

Mr. JAMES RIDDEL (Plymouth) agreed that full investigation of all cases was certainly the ideal but it was not always easy to achieve. One might be accused of being in almost the same position as a case of carcinoma occurring in the stump of cervix left behind after subtotal hysterectomy. He asked, Was this common? Is it as it was he would be tempted in future to perform panhysterectomy more frequently.

Professor F. W. MARLOW (Toronto) expressed his belief that in Canada more early cases of cancer of the uterus were coming under observation as the result of the teaching on this subject and the enlightenment of the public. Unfortunately however there were still a great many inoperable cases. As to the preoperative use of radium, he stated that it should be remembered that, in addition to cancer, infection was practically always present, and it was no doubt due to this fact that reactions following the use of radium were sometimes of a serious nature. He stated that cauterization and cooping of the cervix as a preliminary operation was less likely to be followed by a marked reaction in the surrounding tissues and provided an efficient method of cleaning up the cervix and getting rid of the infection also that at the radical operation about fourteen to sixteen days later it was often found that the uterus had actually loosened up to some degree. He also spoke of the great importance of prophylaxis in respect of cancer of the cervix, and urged that if greater care were given to the diagnosis and efficient treatment of cervical catarrh and cystic disease, which undoubtedly rendered the cervix prone to the development of cancer, more lives would be saved than by the performance of formidable operations after cancer was well established. More especially was this true if they regarded cancer as being due to an infection which more readily became active in sites of chronic irritation and infection. It was also urged that Mr. Cameron's reported cases of tubal cancer should be carefully noted since this condition probably afforded the explanation of some cases of malignant disease in the pelvis, where uterine or ovarian cancer could be fairly well excluded in diagnosis.

Dr. TARGEMAN MURRAY (Newcastle-on-Tyne) congratulated Mr. Bonney on his results, which represented the best that surgery could do for this disease. Better results would be obtained if the cases were diagnosed earlier. The sound training of students was most important, but the women themselves were chiefly responsible for the large number of cases seen which were quite inoperable. Ignorance, fear and even shame all played a part in making them seek advice as a last resort. There was no reason why the public should not be educated on these matters as freely as they were on venereal disease. Gynaecological examinations should be carried out in the privacy of the patient's home. Women seeking advice often did not expect to be examined and were not prepared for one should it be suggested. No pelvic examination was thorough unless it included an abdominal examination as well, and this could best be obtained in the patient's own home. Unless the home conditions were suitable the patient should be sent to hospital. He called attention to the importance of examining pregnant or recently delivered women complaining of irregular bleeding, having met a number of cases in which the condition was due to cancer.

Professor WATSON, in reply, said that it had been very satisfying to find that opinion throughout the discussion had been practically unanimous. The solution of the problem lay mainly in the thorough education of the student. Dr. Marlow had very rightly laid stress upon the proper prophylactic treatment of cervical lesions. He quite agreed that bleeding during pregnancy should always call to mind the possibility of carcinoma being present.

Mr. VICTOR BONNEY, in reply, deprecated the criticism of the results he had obtained in cases in which the regional glands were carcinomatous. It was true that the outlook for these patients, as a class, was much less good than for those whose regional glands were not carcinomatous, but whatever views might be held as to the efficacy of radium in cases where the regional glands were not carcinomatous, it was certain that when the glands were carcinomatous radium was incapable of effecting a cure. The advocates of radium would no doubt say that the carcinomatous regional glands could be treated by deep x-rays, but his experience of this treatment both for primary and secondary growths, was most disappointing. He had seen many cases in which the growth was certainly delayed, but never once had he seen a cure. In short, the only cure for cases in which the regional glands were carcinomatous was operative removal, and this being so he saw no point in arguing against the results of a treatment which, though very far from ideal, was yet the only treatment which held out any hope. He submitted that to have cured 25 per cent. of these cases was an unexpectedly great triumph. If it were possible to recognize before the operation those cases in which the glands were carcinomatous, he would not adversely criticize the surgeon who considered that, as a group, they were not worth operating on, even though the risk of the operation was great and the chances of permanent cure relatively small. He should not agree with such a view himself, but it would be a matter of personal opinion which every surgeon would have to decide for himself. It was however, impossible to make such a decision, not only before the operation but even during the operation for until the glands were removed it was in many cases impossible to say whether they were carcinomatous or not. No one more than himself desired to find a method of treating carcinoma of the cervix better than operation, but there was no sense in the advocates of radium carpentering the results of surgery until they had produced a series of figures comparable with those he had just put before them. It was in use trading on foreign cases for such figures. A study of the literature showed how entirely discordant they were. What was needed was the publication of a British series of not fewer than a hundred cases treated by radium, in all of which at least five years had elapsed between the date of cessation of all treatment and the date of publication. The interval that had elapsed since the cessation of all treatment was of prime importance. There was a great difference between keeping a patient alive with carcinoma and curing carcinoma. When such a series produced from a reliable British source, gave a better cure rate than he had obtained by operation he would immediately cease to operate any longer and hand over all his cases of cancer of the cervix to the radiologist.

Mr. CAMERON (Glasgow), in his reply, said that his views in regard to operation and irradiation were exactly the same as Mr. Bonney's, so that there was no need to reiterate them.

SECTION OF PATHOLOGY AND BACTERIOLOGY

DISCUSSION ON FILTER-PASSING VIRUSES

[The following remarks, with Dr. Gye's reply, had not been received when the papers and general discussion on filter-passing viruses were published (August 1st, p. 189).]

Dr. J. A. ARKRIGHT said. As a general comment on the discussion it seems to me that there should be no assumption that the viruses known as "filter-passers" are all of a similar nature. In regard to many of them it may be said that we have little reason to regard them as similar except our ignorance of their nature, including our inability to see them. Next I should like to express my unbounded admiration for the work of Dr. Gye and Mr. Barnard on the cause of cancer. This does not mean that I think there will be no criticism of their interpretation of the experiments they have published. Whilst their facts are no doubt correct the hypotheses will, I feel sure, be subjected to critical examination. There are two points on which I should like to ask Dr. Gye to give us further enlightenment. The first question, which it seems

almost certain he will answer in the affirmative, is whether the experiments, in which Rous's fowl sarcoma was produced by the inoculation of a chloroform-treated "sand-filtrate" of one of these tumours together with a "sub-culture" of the Rous "virus" were controlled by giving parallel injections of material in which un inoculated culture medium containing fresh chicken embryo was substituted for the "subculture." Another point which strikes one is the resemblance between the chloroformed sarcoma extract which Dr Gye does not regard as living and calls the "specific chemical factor," and some of the so-called "filter-passing viruses" which are associated with various other diseases. Some of these are remarkably resistant to adverse conditions. For example, the virus of vaccinia is well known to have a high resistance to chloroform and ether and the virus of foot and mouth disease is known to resist drying over sulphuric acid, and was found by Loeffler sometimes to withstand 1 per cent

alcohol for many weeks. If the "specific factor" is really a simple chemical substance, as Dr Gye believes, it is remarkable that it should be able to determine the kind of cell in the new growth resulting from an inoculation and the kind of animal in which the virus can cause growth.

Dr Gye said. The answer to Dr Arlwright's first question is "Yes." Parallel experiments have been done many times with negative results. The second question is more difficult. The interpretation put upon the experiments has been founded upon first, cultures from chloroformed extract fail secondly direct dilution experiments are all favourable to the interpretation given, and thirdly the assumption that the effective factor is another virus again lead us to the position that strict specificity is dependent upon a virus. In short the simplest and most direct interpretation has been put forward, and this is supported by available facts.

TWO CASES OF TUBERCULOUS SPLENOMEGALY

BY

E. ROCK CARLING, F.R.C.S.,

A.D.

J. A. BRAXTON HICKS, M.D.

(From the Laboratories of the Westminster Hospital)

THE title "Tuberculous splenomegaly" has been chosen to avoid the implications of the word "primary" sometimes used in the description of this form of tuberculosis.

CASE I

Maria C., aged 65, was admitted under the care of Mr W. G. Spencer—to whom we are indebted for permission to publish the notes—on November 10th 1919.

There was but a five weeks history of progressive wasting and muscular weakness with no particular complaint or symptoms other than those due to the presence of the splenic tumour. She had noticed for two or three years that her abdomen was getting bigger. She had had varicose veins in the left leg they had ruptured three times. She was pallid her atrophic skin had a subicteric tint. The tumour filled the whole left upper and lower quadrants and the right lower quadrant of the abdomen. The right side of the tumour on which the notch was recognizable, was somewhat mobile whilst the left side of it seemed to be deeply anchored.

Laparotomy had been performed in 1911 at St Thomas's Hospital for removal of an ovarian cyst and the appendix no enlargement of the spleen was noted at that time a fibroma had also been removed from the left labium.

There was irregular fever on admission the temperature ranged from normal to 102° pulse 88 to 104.

The blood count on November 18th 1919, was as follows:

Serum to corpuscles	1 to 1
	65%
	0.8
	8200
Polynuclear neutrophils	70% 74%
Eosinophils	4%
Lar. mononuclear	10% 26%
Small mononuclears	16%

The Wassermann reaction was negative.

Splenectomy was performed by Mr Spencer on November 25th. There were no adhesions of the spleen but the transverse colon was firmly attached to the anterior parietal peritoneum. In dealing with the horizontal ligament the tip of the tail of the pancreas was removed and the ligatured pedicle was therefore fixed in the wound.

On the day after the operation the temperature was normal but respirations were 40 to 50 on the next day the pulse was 124 temperature 101.2°, respirations 36. She died on November 28th 1919.

The necropsy notes state Emaciation no peritonitis along splenic vein five enlarged lymphatic glands liver greatly enlarged (73 oz) pale and firm on section no amyloid reaction. Small subperitoneal cyst on surface of left lobe. Kidneys pale and firm on section right 6 oz left 3½ oz. Left ovary absent right small. No tubercles on peritoneum diaphragm or parietal pleura. On visceral pleura a few grey tubercles. Lungs scattered grey miliary tubercles more on right side than left lungs otherwise well aerated not engorged. Castrointestinal tract nil.

Microscopical.—Lungs, emphysema pneumoconiosis tuberculous. The liver and lymphatic glands showed tuberculous kidney cloudy swelling no tuberculous.

The surface of the spleen (which weighed 72 oz) was smooth there was no thickening of the capsule scattered over the surface were a number of pea-size yellow areas each surrounded by a zone of hyperemia. On section the spleen which was very vascular showed similar yellowish areas with hyperaemic zones some one to two inches in diameter no caseation.

CASE II

Lizzie S., aged 28 a patient of Dr Gordon Ward was sent to one of us in April 1920 complaining of weakness and constitutional fatigue of the presence of a lump in the abdomen noticed for the first time six months before and associated with discomfort sense of weight and dragging in the left side. She had lost weight. She had also a seropurulent nasal discharge due as reported by Mr de Santi to advanced left sided atrophic rhinitis with crust formation. The spleen firm and apparently smooth to the touch occupied the whole left side of the abdomen to three or three and a half inches below the umbilicus there was no enlargement of lymphatic glands to be detected the liver was but slightly if at all larger than normal no other abnormal physical signs could be found. There was irregular fever the temperature reaching 99.6°, 100.8°, 100.2° and so on in the evenings.

The blood count on April 30th 1920 was as follows:

Serum to corpuscles	1 to 1
Haemoglobin	90%
Red blood corpuscles	5 820 000
White blood corpuscles	4 600
Polynuclear neutrophils	56% 59%
Eosinophils	3%
Lar. mononuclear	27% 42%
Small mononuclears	14%

Splenectomy was performed (E.R.C.) on May 1st. The spleen was adherent to the diaphragm and elsewhere but presented no considerable difficulties in removal a cigarette drain was employed. The stitches were out on May 9th and she was discharged on May 20th.

A blood count taken on May 7th, 1920 was as follows:

Serum to corpuscles	1 to 1
Haemoglobin	68%
Red blood corpuscles	4 430 000
Colour index	0.8 approx
White blood corpuscles	10 500
Polynuclear neutrophils	69% 70%
Eosinophils	1%
Lar. mononuclears	17% 25%
Small mononuclears	6%
Transitionals	6%
Basophils	1%

Dr Gordon Ward informs us that for some weeks after discharge she picked up nicely but that she died six months later of generalized tuberculosis.

The spleen weighed 4 lb. It closely resembled a spleen from a case of miliary tuberculosis but on a very much larger scale. The surface was studded all over by raised tubercles surrounded by small zones of hyperemia. These tubercles were of considerable size being generally the size of a large pin's head. On cut section also the very free distribution of the tubercle was well seen and the contrast between the very numerous tubercles of this spleen and the comparatively few of Maria C. was noteworthy. Another contrast was the comparatively smooth surface of the spleen of Maria C. and the nodular surface of this case.

Lizzie S. There were no areas of caseation.

In considering these two spleens, it was found that they had certain characteristic features in common, but presented certain well marked differences. A feature common to both is vascularity, with a change of the ordinary splenic structure into that of a moderately loose-meshed sponge, of which the interstices are for the most part filled with blood. Indeed in one spleen (I. S.) so loose is this meshwork that parts of it resemble lung tissue at the first casual glance. Another similarity is a general increase in the interstitial fibrous connective tissue, in M. C. this process is uniform diffuse in L. S. there are in addition, well marked areas of local fibrosis where the tubercles are "healing" or "granulated." In both spleens, whilst some typical "granulated" formations are found, there are differences in other which as a histological study, are of great interest. In

L S, who is aged 28 years, the "tubercles" are numerous and stand out boldly, the central giant cell being surrounded by endothelioid cells of fibroblastic tendency, for the fibrous areas mentioned above are most marked where the giant-celled formations are most numerous. In M C, who is 65 years of age, the typical "tubercles" are few and far between, but scattered throughout the section are large numbers of "lonely," somewhat atrophic, giant cells, with no tissue reaction (fibrosis, etc.) around them. This latter appearance has been observed not infrequently by one of us in senile tuberculous of lymphatic glands, and is, after all, what one might expect in old age where tissue reaction to infection is often half-hearted and atypical. It is further of interest from this point of view to remark that, of the sections examined, it is only in those of M C that necrosis of tissue was found. Although sections were diligently searched for tubercle bacilli by three competent observers, none were seen.

These two cases well illustrate the type described by Winteritz in his study of fifty-one examples. The comparatively mild symptomatology, the size of the spleen, the existence of tuberculous in the liver and lymphatic glands, leading to it, and in the lung in the one case, the supervision of generalization in the other, despite splenectomy (performed, as Dr. Ward suggests to us, "too late") and the microscopic findings, are all in accordance with the general picture. No inoculation experiments were performed in our cases.

Although no definite primary focus was found and although the splenic lesion dominated the clinical picture and was the source of spread, we hesitate to accept the term "primary tuberculous" of the spleen. From a surgical point of view the conclusion to be drawn from a study of these cases is that splenectomy should be performed early, and that, for what it is worth, irregular fever with splenomegaly should suggest tuberculous, but we admit that though, having seen one of these cases recently, one of us (J. A. B. H.) did suggest the diagnosis in the other, yet in the presence of the splenomegaly syndrome we are still very much in the dark as to diagnosis and rational treatment.

DIFFICULTIES IN THE DIAGNOSIS OF CEREBELLAR ABSCESS

BY

R. SCOTT STEVENSON, M.D. EMER.,

SENIOR ASSISTANT SURGEON METROPOLITAN EAR, NOSE AND THROAT HOSPITAL ASSISTANT EAR AND THROAT DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL, LONDON

THE signs and symptoms of cerebellar abscess, in a typical case, are very definite, and it may be imagined on reading the textbook descriptions that the diagnosis of a case should present few, if any, difficulties. In practice, however, the diagnosis of a cerebellar abscess is often very difficult. So experienced a surgeon as Mr. J. S. Fraser said of his own cases, not long ago, that in only four out of eight cases of cerebellar abscess was the diagnosis sufficiently certain at the time of operation to enable the surgeon to proceed to the opening of the abscess.

Intracranial abscesses are almost always the result of chronic, rather than of acute, suppuration of the middle ear, and cerebral are much more common than cerebellar abscesses. Neumann found, in a total of 532 that 336 were cerebral and 196 cerebellar abscesses and Hunter Tod, in a collection of 100 cases, found that in adults cerebral abscess occurred in 65 per cent of cases and cerebellar in 35 per cent.

The onset of an intracranial abscess is gradual, and as the symptoms arise during the course of chronic suppuration of the middle ear, the patient is not usually seen at an early stage by the otologist. The chief symptoms, which are due to intracranial pressure, are headache (usually dull and not, as in meningitis, excruciating), insomnia, a sub-

normal temperature, a slow, bounding pulse, vomiting and optic neuritis. It is usually taught that a subnormal temperature and a slow pulse are typical of intracranial abscess, but in intracranial abscess secondary to middle ear suppuration a rise of temperature often occurs, and the pulse rate may not be slowed. Again while the presence of optic neuritis may be evidence of increased intracranial pressure, its absence does not negative intracranial abscess. It is said that in cerebellar abscess the vomiting and the optic neuritis are more marked than in cerebral abscess, but, on the other hand, both of these symptoms may be absent. Headache is usually stated to be more severe, persistent, and localized in cerebellar than in cerebral abscess, but mental dullness is much less marked. A staggering gait, vertigo (which seems to be quite independent of the ataxia) and nystagmus, are all symptoms which are usually considered to point definitely to cerebellar abscess, but they may also be symptoms of labyrinthitis. In the latter, however, the ataxia and the nystagmus tend to subside, while in cerebellar abscess they are inclined to become more marked as time goes on, is usually absolute in labyrinthine inflammation, but the hearing may not be affected in cerebellar abscess. Sometimes in cerebellar abscess there are no disturbances of equilibrium. Nystagmus is often absent in cerebellar abscess, but, on the other hand, it would hardly be wise to make a definite diagnosis of cerebellar abscess in the continuous absence of nystagmus. Barry has shown that in a cerebellar lesion the patient first points outward with the arm on the affected side, and after vestibular irritation (induced by irrigating the ear of the opposite side with cold water) the pointing deviation of the same arm continues towards the same side, whereas in a normal person the first pointing of both arms which results is towards the opposite side. Unfortunately these changes in pointing accuracy are not constantly present in cerebellar abscess, and their absence does not exclude it.

The difficulty of making a diagnosis of cerebellar abscess is well illustrated by the cases of two patients on whom I have operated recently. The first who presented typical symptoms and signs of cerebellar abscess, proved to be a case of extradural abscess in the middle fossa, with chronic perilabyrinthitis, while the second, a case of cerebellar abscess, was diagnosed as a case of acute mastoiditis only.

CASE I

History.—J. M., a man aged 34, came to hospital complaining of giddiness and of intense pain on the left side of the head, which had prevented him from sleeping for four nights. The pain had begun a week previously, radiating down the left side of the face and settling below the left ear. Two days after the onset of pain he had four attacks of giddiness at his work without losing consciousness, and on his way home he vomited twice. Since then he had felt rather dazed but had not vomited again, but had felt inclined to do so several times.

Examination.—The left ear was discharging, and the patient stated that it had discharged from time to time for the past sixteen years. There was a large perforation of the left tympanic membrane and a considerable quantity of pus was exuding. There was tenderness over the point of the mastoid. He could hear the conversational voice at a distance of 3 feet but not a whisper. Rinne's test was negative and bone conduction was prolonged fifteen seconds. The fistula test was negative, he first pointed with the left hand to the left. There was definite nystagmus to the left, the margins of the optic discs were blurred. His gait was ataxic, his temperature was 102.4°, his pulse rate 80 and his respiration rate 20.

Diagnosis.—A diagnosis was made of cerebellar abscess complicating suppurative mastoiditis on the left side, and the patient was accordingly admitted to hospital for operation.

Operation.—Next day I performed a radical mastoid operation on the left side. The mastoid cells were full of pus and pus welled up from the antrum when it was opened up. Beyond the antrum the bone was necrotic so I continued to clear it away and as pus under pressure I enlarged this opening, but there was no bulging of the dura and there did not appear to be any intracranial inflammation. The lateral sinus appeared to be healthy and there was no track towards the cerebellum. I accordingly made a metal flap, bipped the wound and drained the cavity with a wide rubber tube in the external meatus and a gauze drain to the postaural wound, which I closed partially.

The patient's temperature fell to normal in five days. When he got out of bed at first he complained of giddiness, but this

gradually disappeared. He remained in hospital for a month, and made an excellent recovery. When I saw him recently he was quite well, and his hearing was fair; he had had no further giddiness. The post-aural wound soon healed, and although there was a slight discharge from the ear for a month or two it is now dry.

In this case the symptoms attributed to cerebellar abscess were caused by the intra-aural pressure of a large extradural abscess, and also by chronic perilymphitis, which subsided as the mastoid suppuration cleared up. A more thorough examination of the vestibular apparatus would probably have helped towards a more precise diagnosis, but it is obviously impossible to carry this out in the case of a very sick man with a temperature of over 102°.

CASE II

History—D B, a man aged 52, was sent into hospital by his doctor as an emergency acute mastoiditis. He complained of very severe pains in his head which he had had for six or eight weeks sometimes at the vertex but mostly behind the left ear. He had been unable to sleep or to work for over a week. He had never had any ear discharge and was not deaf. Two days before he came to hospital a swelling had appeared behind the left ear.

Examination—The left mastoid region was swollen, and tender to the touch. There was no discharge from the left ear, and the tympanic membrane was opaque but otherwise seemed normal. Rinne's test was positive and the hearing was apparently unaffected; there was no vertigo, no nystagmus, no optic change apparent. His temperature was 99.6°, his pulse rate 112, and his respiration rate 24.

Diagnosis—A diagnosis of acute mastoiditis on the left side was made, and an immediate operation was decided upon.

Operation—I made the incision for the Schwartz mastoid operation on the left side, and pus appeared at once when I reached the bone. The mastoid cells were necrotic and full of pus more so towards the tip of the mastoid process. I tracked the pus down wards and behind the lateral sinus to the posterior fossa of the skull, from which pus welled up as I made a wider opening into it. The dura mater over the cerebellum was bulging and I made a crucial incision over the bulge through which a small quantity of pus came out. I then opened up the antrum, wiped the wound packed it lightly with gauze through to the cerebellum and left the posterior wound open.

The patient was in hospital for just over a month and left in good health but with a post-aural sinus discharging. When I last examined him three months after the date of the operation this sinus had cleared up and the posterior wound was completely healed. Rinne's test was positive, with the left ear he could hear the conversational voice at 35 feet, and a whisper at 6 feet.

This case presented no symptoms or signs of cerebellar abscess, nor, indeed, of any intra-aural lesion, though perhaps the severity of the localized headache should have made me more suspicious than it did. It is also interesting as being a case of mastoiditis without any apparent middle-ear inflammation (so called latent otitis media), which is rare in adults, but somewhat more common in children.

VACCINE TREATMENT OF SPLENOMEGALY IN CHRONIC MALARIA

BY

R. E. INGRAM-JOHNSON, L.R.C.P. Ed.,

LABU & MS

In the tropics the presence of children with chronically enlarged spleens is always regarded as a source of danger of infection, as the enlargement is evidence of the presence of the malarial parasite in large numbers in the spleen itself, with the possibility of its appearance in the peripheral circulation at any time. The percentage of children suffering in this way is taken as an index of the health of the community so far as malaria is concerned.

Being fully convinced that some antitoxin is formed in the blood of persons who have suffered from true dengue fever, which has a destructive action upon the malarial parasite, I obtained a serum from the blood of persons just recovered from true dengue and experimented with it, by intramuscular injection, upon children with chronic splenomegaly, as I concluded that it would probably destroy the parasite, in which case the spleen would gradually resume, at any rate to some extent, its normal size. Should my conclusions be correct, the shrinkage would prove the presence of the antitoxin.

The photographs reproduced are of the three children upon whom I first tried this method of treatment. They show (1) the line of the splenic margin before treatment, (2) the shrinkage at the date the photographs were taken, (3) the costal margin.

Case A: A boy aged 8 and Case B: a boy aged 5 each received the first injection on October 16th 1924 the second on October

23rd and the third on November 11th. The photographs were taken on December 25th. Case C: a boy aged 13 received the first injection on November 9th 1924 the second on November 16th and the third on November 30th. The photograph was taken on December 14th. I examined this patient again on March 1st 1925 and found the spleen normal in size, but very mobile, as the ligaments were very lax.

These cases were chosen as having enormous spleens, a deficient haemoglobin index, and as having been under the usual treatment for many months without effect. They had no other treatment but the serum after the first injection. I claim to have proved—

1 That an antitoxin against malaria exists in the blood of patients who have suffered from true dengue.

2 That the antitoxin is due to the presence of dead (not artificially killed) dengue germs, thus forming a true vaccine in the blood serum.

3 That this serum, being a vaccine, and having a destructive effect upon the malarial parasite, contains dead germs which must, in life, have had some close connexion with that parasite, or be a modification thereof, even as the active principle of vaccine is a modification of that of variola, as, were there no connexion between the two diseases, malaria and dengue,

it could not possibly have the effect that it undoubtedly has.

4 The vaccine having such an effect on malarial parasites present in the circulation (even though not causing acute attacks of malaria) should, by its presence in the blood, prevent the proliferation of parasites injected into the blood as sporozoites by infected anophelines, and hence should act as a prophylactic against the disease.

5 The logical sequence is, therefore, that by injections of this vaccine artificial immunity from malaria can be procured, the length of time that immunity holds good, and the quantity of vaccine needed to make it absolute, being matters for further experiment.

CASE A

CASE B

CASE C

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL

POISONING BY IVY

A boy, aged 3½ years, was, according to his mother, taken ill on June 20th at midday. I saw him two and a half hours later. He was then in a condition of mild delirium which alternated with stupor. He never completely lost consciousness, and could be roused when he relapsed. During the delirious stage clonic convulsions would come on, and he screamed and cried. No tetanic spasms were observed. He could not stand. He had visionary hallucinations that bulls were chasing him and rats and beetles crawling over him, they lasted for many hours. An intense scarlatiniform rash, most marked on the legs, face and back, was present. There was no vomiting or purging. The pulse was rapid but full and bounding, becoming weaker later. The pupils were widely dilated. The temperature was raised.

Emetics were given but failed to act, and the stomach was washed out. Nothing appeared to be of assistance in coming to an accurate conclusion as to the nature of the poison. I strongly suspected that he had eaten some poisonous substance despite his mother's emphatic declaration to the contrary. Afterwards he was given a stiff dose of castor oil, which was retained, but did not act until some hours later.

The symptoms abated after the wash out, and in about three hours he was fairly well. When the hands acted the cause was discovered—namely, ivy leaves. He had eaten a considerable quantity of these. Next morning he confessed to having eaten the ivy leaves, and a boy who was with him corroborated. The ivy was the common climbing variety.

There are several interesting features about this case. Glaister in his *Medical Jurisprudence and Toxicology* (1915) does not mention ivy as a poisonous plant. I am well aware that the American variety of poison ivy (*Rhus toxicodendron*) may cause dermatitis venenata, an example of which I saw last year from this plant, but in the present case this plant was not the one at fault. Another name under which this particular plant masquerades is *Impatiens naggii*. The variety of ivy which was the cause of all the trouble was the ordinary common ivy, which can be seen climbing on my wall. Another point was the close resemblance which the symptoms showed to belladonna poisoning—namely, the irritation of the central nervous system followed by depression, the widely dilated pupils, and the scarlet rash. The distinguishing point was the absence of dryness of the mouth and throat which invariably follows poisoning by belladonna. In view of the fact that *Rhus toxicodendron* may cause a skin rash it is interesting to note the presence of a rash in the case.

P. H. J. TROTTER, M.B. Edin.

TRANSIENT GLYCOSURIA FOLLOWING SCORPION STING

This note is published with a view to ascertaining whether similar observations have been made in other countries where stings of such a toxic nature are encountered. Scorpions abound in Trinidad, and it is frequently necessary to treat patients who have been subjected to their venomous sting. Two varieties of scorpion are found—the "small brown," which is harmless, and the "large black," which is extremely toxic and dangerous to adults and children. The symptoms develop about half an hour to an hour after the sting showing that the toxin takes some time to develop its action. The earliest symptom is dyspnoea, associated with muscular contractions. The patient passes later into a state of extreme shock with cold, clammy sweats, profuse vomiting of a frothy nature, a slow, thin pulse, and a subnormal temperature. This critical period lasts for about three hours, and the patient then improves gradually and has apparently quite recovered twenty-four hours afterwards. Death rarely ensues. Fits of an epileptiform nature sometimes occur and are apparently due to the toxin. Albuminuria is generally absent. In twelve

out of fourteen cases investigated a transient glycosuria developed and lasted from two to five days. In some the percentage of glucose present was high, ranging according to the severity of the symptoms. In no instance was a special diet enforced. The following three cases illustrate these points.

1. A girl, aged 10, was stung on the leg at 8 a.m. An hour later there were no symptoms and a specimen of urine contained no glucose. She was admitted to hospital at 9.30. At 11.30 the patient complained of pain in the chest with copious salivation and sweating. By 6 p.m. she had quite recovered. The following morning glucose was present to the amount of 0.64 per cent, the specific gravity of the urine being 1008. The next day 0.55 per cent of glucose was present and the specific gravity was 1020. On the following day 0.42 per cent glucose was present, the specific gravity being 1012. The glucose percentage fell to 0.21 a day later the specific gravity being 1016. On the following day it was 0.19 without change in the specific gravity and on the next day glucose was absent the specific gravity of the urine being 1008.

2. A female, aged 18, was stung on the left foot at 10 a.m. and at 2.45 p.m. the urine contained 0.31 per cent glucose, the specific gravity being 1018. She was admitted to hospital at the time with vomiting and epigastric pain, profuse salivation and collapse. An intravenous injection of 5 c.c. of 1 in 1000 potassium permanganate solution was given, improvement began in an hour and a half and by 9 p.m. the patient had quite recovered. On the following morning 0.41 per cent of glucose was present in the urine, the specific gravity being 1010. The next day the glucose percentage fell to 0.3, the specific gravity being 1012, and on the third day glucose was absent the specific gravity being 1010.

3. A female, aged 20, was stung on the leg at 10.30 a.m. and admitted to hospital at 2 p.m. in a collapsed condition with profuse vomiting and muscular pain. Two hours later a specimen of urine contained 0.24 per cent glucose, the specific gravity being 1010. At 4.30 an intravenous injection of 10 c.c. of 1 in 1000 potassium permanganate solution was given, this was followed by improvement within an hour and the patient had completely recovered at 9 p.m. On the following day glucose was absent from the urine, the specific gravity being 1008.

In the three cases glucose continued present after intravenous injection of potassium permanganate showing that the injection did not affect the glycosuria, though I think it had some influence on the acute symptoms. All observations were confirmed by some of my colleagues.

I am indebted to Mr. Sweeny, Junior Chemist of the St. Michael's Sugar Co. Ltd. for verifying my calculations with regard to the percentage of glucose present.

San Fernando, Trinidad.

INJURY DUE TO LIGHTNING STRIKING A WIRELESS AERIAL

This form of trauma seems sufficiently novel to be worthy of record.

On the night of July 27th I was called to see a young woman who was said to have been struck by lightning. Over the right hip she had a large bruise about six inches in diameter with a central area of scorching. She was also suffering from a mild degree of shock. Her clothes were quite unruined. At the time of the accident she had been standing close to the lead in of the wireless aerial. This had completely fused and it seemed to be the flash from the fusing wire which had done the damage. She described it as seeming as though the whole of her right side had caught fire.

Considerable damage had been done to the window frame at the point where the wire entered the house, and bricks had been dislodged from the wall—this although the aerial was earthed by a switch inside the house. Apparently this common form of protection against lightning risks is useless.

The aerial which was of seven strand copper wire, was fused in several places.

SALICYLIC ACID IN EPITHELIAL PROLIFERATION

A solution of salicylic acid in collodion has long been a popular remedy for warts. A similar solution has been found useful in the treatment of moles, warts, especially flat pigmented warts, and other epithelial growths. I have used a 20 per cent solution. It is necessary to scrape off the superficial layer of epithelium in order to allow the collodion to penetrate. A scab forms, which can be removed in a few days, and another application made. The result is very much like that from carbonic acid snow—a soft pliable skin apparently normal. This method appears to deserve a trial in many cases of epithelial overgrowth.

EDWIN CHADWICK

THE happily named Roadmaker Series began with *Lord Lister*, and the latest volume is devoted to *Sir Edwin Chadwick*.¹ In small compass the author, Mr Maurice Marston, gives a singularly vivid and attractive sketch of the life and work of one of the most remarkable men of the nineteenth century. Chadwick was a pioneer in far more than public health. His bounding energy spread itself over many fields, Poor Law, registration of births and deaths (see p 301), factory legislation, employers' liability, the suppression of intemperance, education, physical training, housing, the prevention of crime, the police force, the extinction of fires, the disposal of the dead—these are among the subjects in which his long and busy life was occupied. Nearly forty years ago Sir Benjamin Ward Richardson published in two big volumes many of Chadwick's papers and essays, prefaced by a biographical dissertation, as indicating his view of the scope and importance of Chadwick's writings, Richardson entitled the work *The Health of Nations*. But Mr Marston's little book contains what most general readers of the present day will want, and his picture of Chadwick is all the better in that he makes no attempt to gloss over or explain away the faults which characterized his administrative methods and brought his official life to a close at the early age of 54. That, however, hardly gave pause to his work. Until his death, many years afterwards, his public activities were endless, and, having been born at the beginning of 1800, he survived until within a decade of the close of the century. In fact, he lived so long that when the contemporaries with whom he had quarrelled and fought had passed away, it occurred to a new generation that Chadwick was worthy of a knighthood, and so a C.B. of 1854 was raised to a K.C.B. in 1889—shortly before his death.

In his public health work—in the development of his "Sanitary Idea"—he had for medical colleague on the Board of Health Dr Southwood Smith, who also played a large part in awakening the nation to the need for giving attention to the physical welfare of the industrial population, who, in the new era of steam power and mass production in great factories, deserted their domestic or village workshops, and herded into cities where house accommodation had to be found by them—not for them—under conditions which had not, and perhaps in the practical absence of local government and of awakened public conscience could not have had, any regard whatever to the health of the occupants. Sufficient and safe and systematic water supply was practically unknown, underground drainage also, whilst refuse removal was left to chance, so that in court-yards and closes surrounded by dwellings filth accumulated in heaps until some farmer would buy it for manuring his fields, and the price would be divided among the contributing households.

In these conditions it is not surprising that in the cities epidemics of "fever" were of very frequent occurrence. Chadwick had no high opinion of doctors in general, at least in relation to the prevention of disease, but he did trust Dr Southwood Smith who no doubt was largely responsible for their whole-hearted warfare against epidemics.

Southwood Smith was considerably his senior, and had for long been physician to the London Fever Hospital, which he records was "capable of receiving sixty-two patients." In 1830 he published *A Treatise on Fever*, and the views there set forth express the knowledge and opinions of the period in relation to infectious disease. Typhus and typhoid fever had not been differentiated, and cholera was regarded as air-borne. Fever, under the general term "synochus," he divided into minor and major, these two being further classified "according to the different organs in which the several affections have their seat. Hence synochus gravior with cerebral affection—subacute—acute, with thoracic affection with abdominal

affection, with mixed affection." As to the causes he writes "The immediate, or the exciting cause of fever is a poison formed by the corruption or the decomposition of organic matter. Vegetable and animal matter, during the process of putrefaction, give off a principle, or give origin to a new compound, which, when applied to the human body, produces the phenomena constituting fever" (p 77), and Chadwick, following him, told how, in cleaning ditches, "people were apt to spread the putrid contents over the banks and extend the evaporating surface, so as to generate immediate fever" (Richardson, vol II p 227). As a working hypothesis this was excellent, and there is no need to jeer at it to-day.

At the time when Southwood Smith wrote his book the public mind was occupied, not with health problems, but with the abolition of the corn laws and the adoption of free trade. The age of organized sanitary effort had not begun, and it was long afterwards when Disraeli gave forth as a political battle cry his famous "Sanitas sanitatum, omnia sanitas"—described by his opponents as "a policy of sewage." It was under these unfavourable conditions that Chadwick began his health crusade. Not only were the times inauspicious, but the basal conception of the Board of Health (of which he and Southwood Smith formed half the membership) was a blunder, in the very important respect that the Commissioners were quite independent of Parliament. They were under the wing of no Minister, and had no representative to answer questions or give explanations. As Mr Marston also points out, they had power, when requested by ratepayers, to appoint local boards, but once appointed the central authority had no power to control them. It could only use influence by way of advice, and probably no man was ever less qualified than Chadwick in the art of persuasion. The members of the Board were, says Mr Marston, "doctrine and aggressive."

They trusted no one, believed in no one, and thought that every man's hand was against them. They were apt to seek no advice but their own, and they were often in the wrong. Lord Shaftesbury, one of the four Commissioners, wrote that they had enemies of all sorts—parliamentary agents, civil engineers, the College of Physicians, all the boards of guardians, the Treasury, the water companies, the commissioners of sewers—"they hated us with a perfect hatred." Owing to cholera, the Board's life was extended from five years to six, but then the agitation was successful. In Parliament, writes Mr Marston, "none would have a good word to say for the man who had devoted the greater part of his public life to bringing the atrocious sanitary conditions of the country before their eyes. They saw in him a man fighting against private property and private interests, a man whose energy they distrusted and disliked, a man who was a danger to their comfort and prosperity," so that the *Times* wrote "Mr Chadwick and Dr Southwood Smith have been deposed, and we prefer to take our chance of cholera and the rest, rather than be bullied into health." As to the work of the local boards, the same paper said "It was a perpetual Saturday night, and Master John Bull was scrubbed and rubbed and small tooth combed till the tears ran into his eyes, and his teeth chattered, and his fists clenched themselves with worry and pain." So finished the Board of Health, but Chadwick was a long way from being finished, and his activities, splendid notwithstanding all his defects, continued until the end of his long life, so that now he is remembered as a road-maker—indeed, one of the very greatest road-makers of the nineteenth century.

In closing this notice of Mr Marston's admirable little volume, it happens that the reviewer is able to correct a small error into which both Sir Benjamin Ward Richardson and Mr Marston have fallen. Chadwick stood as a parliamentary candidate for the University of London in 1867, but was defeated, and Mr Marston, following Richardson, says that proposals were afterwards put forward that he should stand as a candidate for Evesham and Kilmarnock Burghs, but that "none of these, however, came to anything." As regards the latter, this is not correct. Chadwick stood for Kilmarnock in 1868, but was defeated. He opposed the sitting member, the Hon E. P. Bouverie. Mr Marston quotes a letter from John Stuart Mill in support of the London University candidature, and the same letter

¹ *Sir Edwin Chadwick (1800-1890)*. By Maurice Marston. The Roadmaker Series. London: I. Parsons Boston U.S.A. Small Maynard and Co. 1925. (Cr. 8vo pp 185. 1 portrait. 4s 6d net.)

was used in the Kilmarnock contest. Bouvier, commenting on it, pointed out that John Stuart Mill was himself in Parliament, and that having so high an opinion of Chadwick he ought himself to stand down and make room for him. The retort was pointed and effective. The fact, brought out during the fight, that Chadwick had a pension of £1,000 a year, was much less cogent, but none the less vote losing. Kilmarnock electors were just as much grieved by Chadwick's £1,000 a year pension as university students of the present day are grieved by the fact that Jenner more than a hundred years ago was voted £30,000 by Parliament. A cartoon showing Chadwick hauling a great dung cart, with his principal supporters pushing it, also played its part, and the fact that he was 58 years of age was much against him. But he made a gallant fight, and it happened that the writer of this notice was one of his poll clerks, thereby earning his first guinea fee, though at the cost of being cooped up all day in a polling booth, instead of wandering at large to enjoy the fun of the last open election before the Ballot Act was passed. That was not the reviewer's last connexion with Chadwick for the old man was glad to indicate his appreciation of young workers trying to build, however clumsily, on the foundations which he had so well and truly laid, notwithstanding opposition and obstruction such as is unknown to students of the present century.

BUCHANAN'S "ANATOMY"

The Manual of Anatomy, by the late Professor A. M. Buchanan, in reaching the fifth edition* may, we think, be considered to have satisfactorily passed through the probation imposed upon such publications, and to be now firmly established as one of the standard English textbooks on the subject.

In forming any judgment upon it we naturally derive considerable assistance from the institution of a comparison between it and other textbooks of the same class. Perhaps the most distinctive feature of Buchanan's book is that, whereas in other books, we believe without exception the subject-matter is arranged according to the systems of the body, here it has been arranged topographically. Much might, no doubt, be said as to the relative merits of the two methods. All, however, that we would here say is that the latter method appears to have two very real and sound advantages. In the first place, it will, we think, be generally agreed that the knowledge of anatomy required in practice is mainly of the topographical variety. In the second place, a student's early instruction in the subject, the fundamental training which he receives in the dissecting room, is on topographical lines, and it would seem to be only natural and proper that his studies should continue along the lines on which they had begun. It is no doubt, too, more easy to convert topographical knowledge of the subject into systematic knowledge, should this be required, than it is to effect the reverse process.

Another important feature which distinguishes Buchanan's *Anatomy* from at any rate most of the other standard textbooks is its smaller size, the diminution being at the expense of minutiae of little or no practical value. The task of deciding what to retain and what to omit must always be one of great delicacy, requiring in a high degree both care and deliberation. The publishers have, we think, been singularly fortunate in obtaining the services of such experienced teachers as the four editors responsible for the present edition. The task has been admirably performed, and the work should prove a real boon to the medical student who, realizing as he must sooner or later the vast amount of knowledge which he is expected to acquire in the course of his curriculum, is not infrequently depressed by his inability to decide with any confidence between matters of real as distinct from matters of problematical value. Not only can we assure him that nothing of importance has been omitted but that matters of serious concern are treated with greater detail than is often the case in books of larger size. We would instance in this connexion

such regions of the body as the mastoid antrum, the parotid gland, the axilla, the perisynovial spaces of the hand, the articulo-ventricular bundle, the biliary passages, and the knee joint. Among the illustrations the plentiful supply of sections is in keeping with the general topographical character of the book, and cannot fail to have a salutary corrective value on what a student has learned from either his own dissections or from those exposed in museums. Text and illustrations have been so amply revised that the book may almost be said to have been rewritten and reillustrated. This statement appears to be particularly true of the parts devoted to embryology, enriched as they are with a very large number of original illustrations. In this section special attention has been paid to the embryological interpretation and explanation of abnormal conditions, particularly those resulting in congenital variations and defects.

We are glad to see that the old nomenclature has been adopted in its entirety, that the nerve accompanying the anterior tibial artery remains the anterior tibial nerve, and that the atlas still revolves round the odontoid process of the axis.

In matters of arrangement, size, discrimination, and nomenclature the volume presents a very agreeable and useful union which cannot fail, we should think, to find much favour with large numbers of medical students. To them we can cordially and confidently recommend it, not only as a reliable and helpful guide through the dangers of the examination room, but also as a simple and practical book of reference throughout the years of their professional life.

THE CEREBRO SPINAL FLUID IN CLINICAL DIAGNOSIS

THE literature on the cerebro spinal fluid has become so extensive, and the multiplication of "tests" and "reactions" so confusing, that a summary in convenient form of the important facts will be welcomed by many clinicians. In *The Cerebro Spinal Fluid in Clinical Diagnosis* Drs J. GODWIN CARMICHAEL and I. ARNOLD CARMICHAEL have given concisely the results of the great experience they have been privileged to obtain in the ward and laboratory of the National Hospital for the Paralyzed and Epileptic, Queen Square, London. The book is written specifically for the guidance of the clinician, and questions of pure technique have been relegated to a subsidiary place, though they have not been neglected. With clinical needs uppermost in their minds, the authors, in the arrangement of their book, have largely followed the plan adopted in the classical monograph of Mestier published in 1912.

The first part of the volume before us is concerned with the general physiology of the cerebro spinal fluid and the changes that occur in disease. Detailed instructions are first given for obtaining specimens of the fluid by lumbar, cisternal, and ventricular puncture, this section is full of useful advice of a practical sort, such as could only be given by operators of long experience at the bedside. The authors rightly remark that lumbar puncture should not be regarded as a routine measure in diagnosis, but should be undertaken only after due consideration of the benefits which may be derived from it. The necessity for special precautions in cases of cerebral tumour and disseminated sclerosis is wisely emphasized. The method of measuring the pressure of the fluid by manometer is described, both for simple lumbar puncture and for combined cisternal and lumbar puncture after the method of Ayer. As an indication of subarachnoid block by spinal tumour and other lesions, attention is called to the absence of the normal rise in pressure on compression of the jugular veins (the Queckenstedt phenomenon). A complete and interesting account is given of the physiology of the formation and absorption of the cerebro spinal fluid, together with the salient facts of the anatomy of the choroid plexuses, subarachnoid and subdural spaces.

The pathological changes occurring in the fluid are then dealt with successively in reference to the pressure, naked-

* Buchanan's *Manual of Anatomy*. Edited by E. Barclay Smith M.D. J. E. Fraser F.R.C.S. F.G. F.R.C.S. W. Wright F.R.C.S. Fifth edition. University Series. London: Lilliere, Tindall and Cox. 1925. (Demy 8vo pp viii + 1702. 810 figures. 5s net.)

3 *The Cerebro Spinal Fluid in Clinical Diagnosis*. By J. Godwin Greenfield M.B. B.Sc. M.R.C.P. and I. Arnold Carmichael M.B. Ch.B. London: Macmillan and Co. Ltd. 1925. (Demy 8vo pp x + 212. 8 figures. 12s net.)

cerebral appearances, cytology, and chemical composition, and the methods of counting the cells are described. It is of interest to note in passing that the authors do not agree with the statement frequently made that the glucose content is increased consistently in encephalitis lethargica. They confirm the value of diminution of glucose as a sign of acute meningitis, and draw attention to the contrast between this diminution and the presence of a high percentage of blood sugar in such cases. Many will agree with the view expressed that the era of the "reaction" in the cerebro-spinal fluid is giving place to more exact biochemical investigation. At the same time the authors subscribe to the value of the colloidal reactions.

A chapter is devoted to the compression syndrome of From, and then individual diseases are considered from the point of view of the changes they produce in the fluid. The last section of the book is concerned with technique. This is a convenient arrangement for the clinician, who is saved the necessity of seeking the significant facts among a mass of technical detail, and increases the value of the book as a work of reference. The volume is completed by a bibliography of modern writings on the cerebro-spinal fluid. This is a book which should find favour with a wide circle of both practitioners and students as an authoritative and practical guide to an important subject.

NOTES ON BOOKS

A NEW number of *Brain* dated June has just been issued. It contains a series of papers which will appeal to the professional neurologist more than to the general medical reader. The opening paper is by Dr J P Martin, who apologizes for introducing a new name, amyotrophic meningo myelitis, on the ground that it is reasonably descriptive of the pathological process with which he deals. This is followed by an elaborate study of the histology of juvenile amaurotic idiocy, by Drs J G Greenfield and Gordon Holmes, it is founded upon work done in the pathological laboratory of the National Hospital for the Paralysed and Epileptic, London. Dr Arthur F Hurst has a paper on the pathogenesis of subacute combined degeneration of the spinal cord, with special reference to its connexion with Addison's anaemia, achlorhydria, and intestinal infection, a subject of which he gave some account in a lecture published in our issue of January 19th, 1924 (p. 93). Dr Otto Sittig of Prague contributes a clinical study of sensory Jacksonian fits, among which he distinguishes several classes. Mr Percy Sargent relates four cases of haemangioma of the pia mater causing compression paraplegia, and adds a report of an example of arterial angioma, a very rare condition.

Sir W M BAYLISS has completed the work of revision of the fifth edition of his monograph, *The Nature of Enzyme Action*,⁴ before the onset of his fatal illness in 1923. The volume has been passed through the press by his son, but no attempt has been made to add to the work by including the advances made in the subject during the past two years. The fourth edition of this work appeared in 1919, and no extensive alterations have been made in the present volume. The monograph is so well known to students of biochemistry that it is unnecessary to describe it at length. It gives an excellent introduction to a subject of great difficulty, and in particular explains very clearly the mathematical laws that have been established in the case of enzyme action. Sir William Bayliss undoubtedly had a peculiar talent for explaining highly complex phenomena in the simplest manner possible, and in this book he showed this gift to a remarkable degree.

The latest of the series of small volumes on the history of science edited by Dr Charles Singer is a book written by J W N SULLIVAN entitled *The History of Mathematics in Europe*.⁵ It is a very interesting account of the development of this science from its first beginnings in Europe down to the invention of the differential and integral calculus a story which the unmathematically minded will enjoy almost as much as the wranglers. Nowadays the mathematician is held in general esteem by his fellows, and he has enjoyed similar respect in the past, a mysterious benevolence which

Mr Sullivan finds difficult to explain. The brief biographies of eminent mathematicians the book contains serve only to increase this esteem, for they reveal the great difficulties the early pioneers had to overcome.

The chief addition made to Mr BERTRAM KERSHAW'S book *Sewage Purification and Disposal*⁶ in its second edition is that it now contains a much fuller account of the activated sludge process of sewage treatment. This and the subject of sludge digestion form the main substance of the ninth chapter. For the benefit of those unfamiliar with the first edition we may add that Mr Kershaw has been for many years the engineer to the Sewage Disposal Commission, that he has had exceptional opportunities for investigating various sewage treatment processes, and that his volume is recognized to be an authoritative textbook on its subject.

Two French authors, Dr JACQUES PARISOT and Dr PIERRE SIMONIN, have written a book⁷ on vaccine therapy in which they describe the methods of preparation of vaccines and the different diseases in which vaccine therapy is likely to be beneficial. It is divided into three parts: the first discusses the theoretical basis of vaccine treatment, the second the actual technique of vaccine therapy, and the third the practical applications of vaccine therapy and the results to be expected. It is a sober account of a subject about which extreme views are frequently expressed. On the one hand the authors for the most part avoid extravagant claims for vaccines, and on the other they are not so foolish as to deny the existence of benefits which fail to secure the support of current theories of immunity. It would have been more easy for the reader to find his way about if the book had been provided with an index.

London has been truly as well as wittily called a province of houses. Most of its inhabitants know very little beyond their road from home to business and what bus to take to popular places of amusement, a few, perseveringly walking home by devious paths, or by deliberate exploration, gain an acquaintance with a district, possibly a square mile or so. Then there are the suburbs and semi-suburbs, unattractive to the walker for pleasure, who prefers to take a train to carry him further afield. A map on a scale sufficiently large to be useful fills too large a sheet to be manageable. What is wanted is an atlas giving a section on each page and provided with a good index. Several map publishing firms have sought to meet this need, and Messrs John Bartholomew and Son, Ltd (Geographical Institute, Edinburgh), have just issued a fifth edition (price 6s net) of their *Handy Reference Atlas of London and Suburbs*. We have tested the index for several rather out of the way streets and have only found it fail once.

PREPARATIONS AND APPLIANCES

Jecomalt

JECOMALT is a preparation of cod liver oil and malt extract prepared by Messrs A Wander Ltd (King's Langley, Hertfordshire). The manufacturers state that it contains 30 per cent of cod liver oil. Jecomalt is a dry powder free from any odour or taste of cod liver oil and has a very palatable flavour. Messrs Wander report extensive laboratory and clinical experiments which seem to show that Jecomalt contains a satisfactory content of vitamins A and B and the antirachitic factor. Jecomalt appears to be a palatable substitute for cod liver oil and the presence of the malt extract increases the nutritive value of the compound and also gives it a high content of the water soluble vitamin B.

Digitalis Leaf

'Tabloid Digitalis Leaf gr. 1 is a preparation by Messrs Burroughs Wellcome and Co (Snow Hill Buildings, London, E.C.1) which should prove a great convenience to many practitioners. Tincture of digitalis is the favourite preparation of digitalis in this country, but many Continental and American workers claim that the powdered digitalis leaf is a superior preparation. Unfortunately the activity of powdered digitalis leaf varies with a number of factors, such as the variety of seed and the methods employed in collection and drying. The preparation of Messrs Burroughs Wellcome and Co is made from digitalis leaves grown, collected, and dried under standard conditions, and furthermore the finished product is physiologically standardized. Thus the same accuracy of dosage can be attained with these tabloids as with tincture of digitalis, and the tabloids have great advantages in convenience of use and in keeping properties. An estimation of the activity of the preparation by the frog method showed that one tabloid (1 grain) was equivalent in activity to 11 minims of standard tincture of digitalis.

THE IDEAL GERMAN

DURING the war there was an uneasy feeling in this country that all was not well with our manhood but so far as we could learn then Germany was satisfied that all was well with hers. And now nearly seven years after victory came on war we seem to have exchanged places while we have apparently resigned ourselves to that part of our population which was relegated to the lowest grades in war time, Germany has become concerned about the racial constitution of her people. Thus, at least seems the just interpretation to place on the fact that a work on the racial nature of the German people written by Dr Hans F R Gunther,¹ is meeting with a remarkable demand in the Fatherland. The first edition was published in Munich in the summer of 1922, in less than a year it had passed into a third edition. It is true that Dr Gunther writes with remarkable force and clarity—he knows how to break the dry bread of anthropology for a popular appetite, but these merits alone will not explain the success of his book. It is to be found in the remarkable gospel which he wishes to instil into the uneasy mind of Germany.

Here Gunther has discovered what is wrong with Germany. All her present misfortunes, he asserts, spring from the bastardization of her blood. She has become "denordized", this calamity overtook her in the nineteenth century when she was so satisfied with her worldly progress. It was then that the true blood of the Nord—the fair haired, blue eyed German of the time of Treitsch—became mixed and ruined by the blood of a stock which penetrated Germany from the East. Of this Eastern blood—most students of human races would call it Alpine or Slavonic—Dr Gunther speaks in the most uncomplimentary manner. It has ruined Germany, it has rounded her heads, darkened her hair, blunted her noses, shortened her faces, thickened her necks, destroyed the athletic and classic lines of her figure, and, what is worse, destroyed the German soul. For the Nordic man, the original German, was the soul of honour and of courage, he glowed with his ideals and enthusiasms, he was supreme in leadership, art, and invention. Whereas this Eastern stock, with its round heads, dark hair, wide and flattened visage—of ultimate Asiatic origin—has a soul that cannot rise above its native parish, destitute of all generous impulses, thinking only of its money bags, it is the stuff out of which cowardice and Bolshevism grow. This is Dr Gunther's diagnosis, and, like a confident and practical physician, he has a definite cure to offer. Germany spent the nineteenth century in becoming "Asiaticized" she must make every endeavour in the twentieth century to regain her original heritage of Nordic blood.

Dr Gunther is confident that this miracle can be accomplished, if only those Germans who have the fortune to retain Nordic qualities will remember their responsibilities and choose mates who will give the Fatherland children of the olden stock. Women with Nordic qualities, who have been said sinners in past times, must do their duty

to the full. The war has hit the Nordic element hard, only life is against it, modern industrialism bears unkindly on it, America has sinned the Nordic cream off the German milk, alcohol, venereal disease, and the wiles of women of Eastern origin threaten the Nord with extinction in Germany. All of these mortal influences can be altered so Dr Gunther believes, if only Germans of true Nordic descent will take thought. They must dedicate themselves for purposes of propagation, they must be regarded by the general population as a special and honoured caste. He evidently believes that the huge element of the population which has inherited Eastern traits of body and mind will acquiesce in such a scheme, because it is one which will bring salvation to the Fatherland. It is to be feared that Love, which laughs at locksmiths, will refuse to alter its smile at the behest of our modern eugenicists.

According to Dr Gunther, the population of Britain is in just as parlous a position as that of Germany. He asks his readers to accept without question the modern doctrine that German and British peoples have been compounded out of four racial elements. He believes—and in this he is probably right—that the Nord forms the basis of both populations, he estimates that in Germany as in Britain, 60 per cent of the total blood is Nordic, but this blood is pure and uncontaminated, so far as concerns Germany, in only 6 or 8 per cent of her population. As to how many pure Nords there are in Britain he hazards no guess, but if we accept his criteria of the type we may lay the flattering unction to our souls that pure Nords are six or eight times as frequent as in Germany. The despised Eastern blood mixes up so Dr Gunther has estimated, 20 per cent of the total blood in German veins, but pure representatives of the Eastern stock make up only about 2 per cent of the population. In Britain we have, according to Dr Gunther, 15 per cent of Eastern blood, this estimate will cause anthropologists on this side of the North Sea some degree of surprise. We differ from Germans—still following Dr Gunther—in what he calls the

"Western" or Mediterranean element. He believes that we have drawn 15 per cent of our blood from the native stock of Mediterranean lands, whereas Germany is indebted for only 2 per cent, but as our author has no high opinion of the Mediterranean stock this is no great gain to us. As regards the fourth element of our racial constitution—the Danube element—the positions are reversed. This element finds its purest representation in the round headed, long faced, big nosed strong chinmed, and tall men of the Tyrol, they almost rival, in gifts of mind and virtues of soul, so Herr Gunther declares, the noble Nord, the German of ancient times. Germany in this respect seems to come off best, for she is said to be as rich in Danube blood as we are in that rather inferior article Mediterranean blood.

In Dr Gunther's pages the whole problem of racial analysis seems so interesting and so simple, his descriptions of the types are so clear and detailed that we are surprised to find, when we pass into the highways and byways and meet our fellow men and women, that it is so difficult to arrive at a satisfactory racial diagnosis of the individuals we meet. Theory and fact seem constantly at war. Fortunately, however, Dr Gunther gives his readers numerous photographs of his types. The essential Nord is to be recognized, not by the colour of his hair or the shape of his head, but by the form of his face and, of course, by his mental qualities. Men who have the facial lineaments of the

¹ *Rassenkunde des deutschen Volkes* von Dr Hans F R Gunther. Dritte umgearbeitete Auflage. Munich J F Lehmann 1923 (Med Bro pp 513 14 plate, 537 figures Paper cover 9s bound 11s)

gent Julius Cæsar is declared to be Nordic, Luden doff is a representative specimen, Viscount Grey is also one, save that his forehead is somewhat wide. We are somewhat taken aback when we find Thackeray, Oliver Goldsmith, Thomas Hardy, and Arthur Conan Doyle cited as representative specimens of the Eastern or Asiatic stock, we find them placed in this category because their faces are wide and somewhat short, also because their noses are undistinguished. Were we to accept such features as criteria of the Eastern stock, we must throw overboard much of our present anthropological cargo. When we find Helmholz dissected into Eastern and Nordic components, a suspicion of hydrocephalus being added to the diagnosis, we begin to wonder whether our author's racial standard is not somewhat arbitrary, when we find classified as Eastern Nordics such men as Ibsen, Poincaré, Luther, Beethoven, Schumann, Schubert, and Schopenhauer, we begin to realize that the Eastern blood is more potent than Dr. Günther thinks. Nietzsche is said to have been Danish Nordic, and yet to the unsophisticated ethnologist his features speak strongly of a pure Slavonic origin.

Dr. Günther's book belongs to political rather than to scientific literature, yet it is very interesting, and will stimulate further observation and thinking. He makes a move in the right direction when he refuses to recognize shape of head as the final criterion of race. He is probably altogether wrong when he supposes that the round heads of Western Europe are any more Asiatic in origin than the long heads. He is probably altogether wrong, too, when he supposes that the spirit of a nation—its moral and political behaviour—depends on its racial constitution. The Norseman of to-day, the modern Spaniard, the valley dwellers of the Tyrol, the Slavonic dwellers or the plains of Poland—representatives of Dr. Günther's four racial components of European nationalities—are all swayed by the herd instinct, they could not live in communities unless they were all of them liable to that psychological state spoken of as swollen head. All modern experience goes to show that such swelling is due less to racial heredity than to national environment—the environment created by professors, preachers, and press. Germany herself is a standing instance of the truth of this statement. The nationalities which made up the German Empire suffered no radical change during the nineteenth century, yet the national spirit became transformed in that space of time. All her racial constituents seemed then to have become slaves to the *Zeitgeist* to an equal degree. Indeed, if Dr. Günther is right in attributing the supreme form of doing and doing to men of the old German or Nordic breed, then they were probably the inglanders in what proved a debacle for the Fatherland. A close study of this book will convince most men that it is dangerous—it has always been hazardous—to yoke anthropological doctrines to national policies. Anthropology may prove a helpful handmaid to the statesman, but much has to be done before she can be accepted as a mistress.

ADDITIONAL BEDS FOR VOLUNTARY HOSPITALS

THE Voluntary Hospitals Commission has now presented its report, and a review of it is published in this issue (p. 304) on the instruction it received from the Minister of Health in April, 1924, to inquire into and report upon the extent of the additional voluntary

hospital accommodation required in England and Wales and the best means of providing and maintaining it. The Commission directed its inquiry "to a consideration of what extensions could be regarded as immediately necessary and capable of accomplishment within a reasonable period," and in thus taking short views in politics it has reaped the advantage of being able to avoid the discussion of many thorny problems which have made heavy demands upon the energies of those, including the British Medical Association, who have attempted to explore the fundamental questions of hospital service. The answers of the Commission to the three branches of its inquiry may be shortly stated to be that the extent of additional accommodation now required in England and Wales is approximately 10,000 beds, to provide it a Treasury grant of £2,000,000, equal to half the capital cost of these beds, is necessary, the other half to be provided from local sources, the local voluntary resources will we are assured, be able to maintain the beds so provided.

The statement that the available hospital accommodation is about 33 per cent short of the present public needs is likely to be generally accepted, and in proportion to this great total of 10,000 beds the various suggestions which have been put forward of saving in detail by co-ordination of hospitals which have vacant beds with those having long waiting lists and in other ways fall out as factors in the solution of the main problem, though each may find an appropriate sphere of influence in lightening the burden of future maintenance. To get 10,000 beds within a reasonable time needs the capital provision of about £5,000,000 within the next few years. Many will probably agree with the Commission that to secure this capital a substantial contribution from public resources is required and some may even think the suggested grant of £2,000,000, in comparison with other operations of the Treasury, a light burden. On these points the decision must be taken on grounds of public rather than of medical policy. It is important to realize that in the opinion of the Local Voluntary Hospital Committees there are local resources capable of bearing an equal or even greater burden, not only in providing a large share of the original capital, but in undertaking the task of future maintenance without having to make a recurring appeal for assistance from Government. If this opinion is well founded, the voluntary system can be regarded as a safe and competent factor in meeting the present needs of the community.

On the questions relating to the future maintenance of the voluntary hospitals, the Commission may have heard much but it has said very little. The establishment of a system of local bodies to afford centres for co-operation in the activities of the voluntary hospitals it regards as a measure the wisdom of which has been proved by experience, and it affirms that as these bodies will in future have to undertake new duties and heavier responsibilities, they will need some measure of reconstitution. It seems to favour the plan of evolution along local lines but states that the direct representatives of the hospitals should not be in a majority, and that a strong independent element has proved valuable and should be maintained. This is a matter to which the British Medical Association has given attention, and a full statement of its conclusions will be found in its *Policy affecting Hospitals*,¹ where it will be seen that the problems with which these local bodies will be called upon to deal go deep into the fundamental interests of both the

¹ *Policy affecting Hospitals* (London: British Medical Association Press, 1924).

citizen and the doctor, and that if the members of the Association are to take their full share in securing prudence in local hospital policy it is necessary to be ready soon and to put their own machinery in an efficient condition

THE HEALTH OF LONDON IN 1924

The most fervent advocate of public economy could not say that the 124 pages of Sir William Hamer's report for the year 1924¹ are too many to devote to the medico-statistical and epidemiological experience of a population of four and a half millions, and some readers will think them too few. The discussion of the epidemiology of typhoid fever, particularly the evidence against smallpox, needed fuller statement to carry conviction, while the suggestive essay on influenza and the influenzal group of diseases is certainly not too long. But it is undoubtedly better literary art to leave the reader wishing for more, and that sensation is usually excited by the reports on London.

The rate of mortality in 1924 was 12.2 per mille of the civil population—higher than that of 1923 (11.4 per 1,000), but lower than the rate of 1922, which was 13.5 per 1,000. The rate in 1923 was the lowest ever recorded, and the increase in 1924 was mainly due to greater mortality amongst children under 5 years of age caused by measles, there was also some increase in deaths at ages over 45 largely due to influenza. Neither tuberculosis nor cancer was appreciably more fatal. Deaths from the former showed an increase of only 35 (deaths in 1923—all forms of tuberculosis—5,285, in 1924, 5,320), deaths from the latter increased from 6,346 to 6,483. The increase in the number of deaths due to cancer (137) is three short of the increase in the number caused by vehicles and horses, which rose to 593 from 453—a percentage increase of 30.9, or of 30.3 if allowance is made for the fact that there was an extra week in the registration year 1924. The percentage increase of mortality from cancer was 2.2. Journalists who dwell upon the alarming increase of cancer might meditate upon the contrast. It is indeed, an interesting psychological question what level an increasing rate of mortality must attain before it is a serious factor in promoting reform. In Great Britain in 1924 motor vehicles caused on the average slightly more than 8 deaths a day, an increase of 24 per cent above the figure for 1923. In the United States of America the average daily tribute to the god of the car was 52 deaths, an increase of 4 per cent over the 1923 quota. The latter is a good deal higher, proportionally, than the British rate. In the city of Baltimore, with a population of less than one-sixth that of London, there were 161 fatal accidents due to vehicles in 1920—more than a third as many as in London in 1924. In Baltimore between 1900 and 1920 the rate increased by 55 per cent. The explanation is, of course, the immense increase in the use of motor propelled vehicles, and it would seem a reasonably safe statistical prediction that the London deaths will increase to about the Baltimore standard—say, to 950 annual deaths within a few years—unless some very special measures are taken.

Of the major infectious diseases, smallpox although only four notified and one unnotified cases occurred among the resident population, deserves mention in the first place. Nobody would describe Sir William

Hamer as a scaremonger, but the facts move him to remark: "Having regard to the special position of London, and the fact that sea-borne traffic is plying daily to and fro between its docks and small-pox infected countries, the need for constant vigilance is apparent, particularly as the surest protection against small-pox is gradually being stripped of its influence by the increasing unwillingness of the population to undergo vaccination and revaccination. If the decline in vaccination continues it is possible that the time is not far distant when a serious epidemic can no longer be prevented. A very practical illustration is provided by the circumstances of one of the notified cases. This concerned a man of 54 associated with a group of cases, three fatal in an extrametropolitan district, all the victims were infected by a person whose condition was not diagnosed."

The future of smallpox in this country should afford the epidemiologist most interesting material, and it will no doubt be unspeakably gratifying to the victims that, to quote Mr. Bernard Shaw, nobody sent the police to force their parents to have the most villainous racial poison we know thrust into their veins. Perhaps however, Nature will treat us more kindly than we deserve in that the change of type may not be sudden, as was the case with scarlet fever many years ago but gradual. If there is a gradual change, deaths creeping up from units to tens and then to hundreds, resort to vaccination will gradually become more frequent, a vast majority of the unvaccinated care nothing about the matter one way or the other, and are susceptible to example. The one danger against which we are utterly powerless is a sudden change of type, wide epidemicity, and high fatality.

Both scarlet fever and diphtheria were more prevalent in London in 1924 than in the previous year—1,563 more cases of scarlet fever and 383 more cases of diphtheria. Sir William Hamer devotes some suggestive pages to the general epidemiology of these diseases, and two of his conclusions are noteworthy. The first is 'that the tendency must be recognized, when sufficiently large populations are passed under review, for epidemics of throat disease to occur in major waves at intervals of some thirty years and for the types of disease exhibited at various stages of these epidemic waves to manifest varying phases'. The second is 'that study of any special preventive or prophylactic measures against diphtheria or scarlet fever in a particular town or tract of country, during any year or series of years, needs to be very carefully conducted and that, while closely scrutinizing what actually happens, a critical eye should ever be kept upon what might have been expected to have happened independently of the special preventive measures newly applied'.

In the section of the report dealing with the school population, anthropometric data are given which suggest that there has been some improvement of physique. "That the height attained by a given generation can be affected by the conditions under which childhood is passed is, Sir William Hamer writes, 'well known to physicians. The condition known as rickets profoundly modifies growth, and when widely prevalent this disease undoubtedly leads to much dwarfing. As all are agreed that rickets is much less prevalent now in London than it was it would not be surprising to find an improvement in the height of the children affecting the eight-year-old children, rather more than the twelve-year-old children, owing to this factor alone.' There was again a slight increase in the percentage of children classed as below normal in nutrition. Some 12,000

¹ London County Council—Annual Report of the Council 1924. Chapters XIII and XIV (Reports for the year 1924 of the County Medical Officer of Health and School Medical Officers).

children were so described—6·2 per cent of the school population, the percentage in 1923 was 5·9, in 1922 it was 5·7, but in the year before the war it was 12·8. Having regard to the economic position the deterioration is not remarkable, indeed, "looking at the comparison of the figures during the past year with those of the pre-war period, it is clear that but for the ameliorative efforts at work the condition of the children in this respect must have been far worse than, in effect, it is."

Upon that hopeful note we may conclude this brief notice of a most valuable public document. There is not much likelihood of any student of the newspapers taking an unduly optimistic view of our national position, it is well to realize that the children are now better cared for than in what some regard as a vanished golden age.

THE GENESIS OF A CRIPPLES HOSPITAL

The Story of Baschurch Miss Agnes Hunt tells with much quiet humour, which masks but does not hide her deep feeling, how the Baschurch Cripples' Hospital came to exist, what were its early difficulties, and how it has grown into the Shropshire Orthopaedic Hospital at Oswestry with 320 beds. Miss Hunt writes impersonally and tells the doings of the superintendents, but nowhere does she even hint that she herself was one of them, and the very soul of the whole undertaking. But this fact has now become so well known that any attempt to respect her anonymity would be futile, seeing that in the next article in this pamphlet the cat is expelled from the bag by Sir Robert Jones, who very properly pays the highest tribute to her achievements. The Baschurch Convalescent Home, as it was at first called, was started with eight patients in 1900, and it is interesting to note that these were treated at first indoors, and that the addition of open-air sheds was made as a cheap and expeditious method of increasing the accommodation, and apparently not as the result of any deliberate consideration of what had already been done elsewhere in the open-air treatment of surgical tuberculosis. Yet the erection of these sheds, built with materials pilloined by Miss Hunt from her brother's stables, was the beginning of the work which rendered Baschurch famous throughout the surgical world. Unfortunately for Miss Hunt, but fortunately for the cripples, she herself became lame, this misfortune brought her into contact with Sir (then Mr.) Robert Jones, and she started the home in a large old-fashioned farmhouse at Baschurch in Shropshire. At first Miss Hunt took the cases to Liverpool by train and endeavoured to be seen, and if necessary operated upon, by Sir Robert Jones, but in 1904, when he became surgeon to the home, now a hospital, he visited at regular intervals, performing operations—at first in a very makeshift theatre—and prescribing treatment. Miss Hunt was quick to take hints and to learn the principles of orthopaedic surgery, and because so expert that it would hardly be too much to say that she was univalled in the application and care of splints and plaster-of-Paris, and no mean diagnostician in cases of deformity. As Baschurch became known the number of cases seeking admission increased, and, despite lack of funds, the hospital was enlarged again and again, until, in 1914, it held 150 patients. During the war it became No. 14 V.A.D. auxiliary hospital, and, despite the rigours of the War Office, which are described with the unfading humour which seems to have supported the superintendents in many emergencies, it was able to do good work. In Sir Robert Jones's contribution he describes his first meeting with

Miss Hunt, then herself on crutches, but in charge of six children lying upon a railway truck. He pays a well deserved tribute to her foresight, courage, and ability, which have enabled her to render such great services to humanity. For not only is she to be credited with showing that the open-air treatment of children suffering from tuberculous disease of bones and joints is practicable on a large scale in this country, but to her is due the idea of local clinics, where relapses are prevented and early diagnosis made of crippling diseases, thus by early initiation of treatment shortening its duration. Early in the history of Baschurch Miss Hunt foresaw that the success of the scheme would largely depend upon the supply of an adequate number of properly trained nurses and sisters, and she and her coadjutors began to train probationers in the methods and preparation and uses of appliances which had been successful there. The nurses and massenses trained at Baschurch have since been in great request as the scheme for the cure and cure of cripples has developed. As is well known, the county organization first established in Shropshire is being repeated in other parts of England, and we are justified in hoping that in the near future the care and cure of all cripples will be provided for throughout this country. The qualities which made Baschurch possible to a master spirit are a fresh mind that looked on things in an unconventional way, and a will to which what seemed impossibilities were only difficulties to be surmounted. Miss Hunt was fortunate in her co-workers, to the memory of one of whom—co-superintendent and co-founder, Miss Selma Goodford—she pays an eloquent tribute. Miss Goodford died in 1920, and in memory of her a chapel has been erected at the new hospital at Park

THE REGISTRAR GENERAL'S ANNUAL REPORTS

EDWIN CHADWICK (whose biography is reviewed at page 295) performed one of the most notable services in his notable career when he succeeded in getting the Government of the day to establish by statute the office of Registrar-General, with all its duties of recording and publishing the vital statistics of England and Wales. Also he was most fortunate in achieving the appointment, in 1838, of Dr. William Farr as the medical statistician of the new office. Service was thereby done, not only to England, but to the world, which has, each nation in its own way, adopted and followed more or less closely the example set by Dr. Farr. But with passing time the amount of material requiring to be set forth and elaborated in detail by Farr's successors has so greatly increased that the huge foolscap volume, issued for a number of years, was apt to be viewed with dismay or even repulsion by any but the most enthusiastic student. In recent years the scheme of publication has been changed, and the reports have been replaced by three smaller separate volumes of octavo size, the whole being entitled "The Registrar-General's Statistical Review." One of these relates to civil and social conditions which are not in question here, for only the other two are usually needed for medical statistical purposes. But even these are costly to produce, and the price of £1 hitherto jointly charged for the two has tended to limit their circulation and so restrict their usefulness, at the same time that their production has involved a heavy outlay. Every contributor to medical literature knows the comparatively high cost of a limited number of reprints—or offprints, as is perhaps the more strictly proper term—and how much the printer's price per copy is diminished when a larger number is required. Influenced by such considerations, and at the same time impressed by the urgent need for public economy, the Minister of Health has now submitted a proposition towards the adoption of which he requires and requests the co-operation of all concerned—public health authorities,

¹ *The Story of Baschurch* By A. G. Hunt. With contributions by Sir Robert Jones and other Oswestry. Caxton Press. Price 6d.

bords of guardians, Insurance Committees, and whoever else may find value in the possession of these volumes prepared by the Registrar-General. As mentioned briefly in our last issue, the proposition is that the combined price of the two shall be reduced from 20s to 12s 6d annually if a subscription order for the next five years is given by such a number of public bodies or individuals as will make the project financially feasible. In circulars explaining the scheme it is pointed out to public health authorities that they may legitimately out of their funds provide the volumes for their medical officers, and that would be true also in the case of the other classes concerned. The scheme, it seems to us, cannot fail to command hearty approval. No municipal library, no library of any institution or organization relating to health and disease, can be elementarily complete without having these works on its shelves. Nobody would want to read right through the hook of tables any more than he would want to read right through a dictionary. But everyone needs a dictionary for reference, and every committee and every official dealing with any section of health administration ought to have immediately available the Registrar-General's volumes both of tables and text. Emulation is the soul of progress. Health rivalry is healthy for the localities which engage in it. Each authority wants to know how its birth rate and infantile and all-age death rates compare, not only with those of England as a whole, but with those of other areas, both similar and dissimilar in the conditions presumably influencing local health. This applies not merely to comparison of age period with age period but of disease with disease, whether infectious or non-infectious. It applies also to comparison of successive periods of time, year with year, decade with decade. These are mere truisms and need not be multiplied, indeed they hardly require statement, but possession of the Registrar-General's publications is at the basis of them all, and every health officer should settle down once in a while to dip into and study one part or another of the immense mass of material contained in these reports. They will be found rich in suggestion as regards many a problem affecting his preventive work. It is true that to do justice to such study he requires intervals of leisure from the multitudinous duties, old and new, imposed on him by statute and regulations, but it is not good for him to occupy more than a reasonable portion of his time with child welfare, maternity welfare, school medical inspection, venereal disease clinics, and other such duties, notwithstanding the importance of each and all of them. And when he does chance to have a free interval he might well devote it sometimes to browsing quietly in the field of problems provided by the publications periodically sent out from Somerset House. The undertaking to subscribe for the two volumes for five years at 12s 6d a year should be sent to the Registrar-General, Somerset House, London, W C 2. If the special terms are confirmed they will apply to the 1924 edition now in the press.

PILLS, POLITICS AND RELIGION

To those who in these days feel an inclination to disturb the clean-cut outline of medicine as a positive science and merge it with the supernatural, we commend the study of the native medico-religious systems of India. In that country medicine is based on religious doctrine, and is part and parcel of a complicated philosophical theory. The inconveniences of the combination are notorious, and the despair of medical reformers, innovations and improvements are liable to be regarded as unorthodox, and are tested in the light of antiquated dogmas dating back thousands of years, new facts and new ideas collide with religious convictions, and progress is blocked. Let us, in this country, keep our science positive and its sphere well defined. There is, indeed, little fear of our falling into such a slough. Despond is exhibited by Indian medical matters, but we

do well to remember that a little leaven leaveneth the whole lump. It appears that Indian medicine is also plagued with the contamination of political propaganda, an ailment of which may be obtained from the following quotation from an advertisement of Ayurvedic drugs. The advertisement is that of an evidently reputable firm of Swadeshi pharmacists, and is printed on the blank sheet of the prospectus of a State lottery. Tea, which is stated to cure all troubles of the stomach and lungs, heads the list of important drugs, and a stirring appeal is made to the patriotic instincts of Indians on this subject. "We strongly recommend everybody to use our Swadeshi Ayurvedic tea" (prepared, it is stated, in accordance with the precepts of the holy books) "in the interest of our country and countrymen. Our tea will save you from the habit of the foreign injurious tea." "Foreign tea is produced by our own countrymen working as labourers whose heart-rending sufferings are worldwide known. If you are a true Indian, you must at once relinquish that poisonous and unholy tea to achieve our countrymen from slavery." The religious element is also clearly discernible in this effort to promote the buoyancy of the drug market by linking it up with the present political unrest. We have nothing to say against the religious convictions of the Indians, we merely draw attention to the undesirable mixture of medicine and metaphysics, to say nothing of political propaganda. Ayurvedic itself is an interesting study abounding in quaint details, as witness the following from the same source as the preceding quotation. "Gonorhoea Churan—Excellent for every kind of Gonorhoea and gives coolness to a burning heat." The latter expression evidently refers to a painful sense of remorse that follows the perpetration of a wicked deed, and is perhaps borrowed from the New Testament—"did not our heart burn within us?" With all its faults there is a quaintness about the Ayurvedic philosophy which renders it strangely attractive.

ANIMAL EXPERIMENTS IN 1924

THE annual report for 1924 of the inspector, Dr J A Giles, under the Act for regulating experiments on living animals has been issued. It is founded on three tables—one showing the number of registered places, the second a number of licensees, and the third the number of experiments performed. Twenty-six new places were registered and four places were removed from the list. Licensees are restricted to the place or places specified on their licenses, with the exception that permission may be given for the performance in other places of inoculation experiments with the object of studying outbreaks of disease occurring in remote districts, or in circumstances which render it impracticable to perform the experiments in a "registered place." The total number of licensees was 1,042, but only 803 performed experiments. The experiments fall broadly into two classes. Of 8,053 experiments comprising all those in which any serious operation was involved, 4,324 were performed under the provision of the Act directing that the animal must be kept under an anaesthetic during the whole of the experiment, and must, if pain is likely to be felt after the effect of the anaesthetic has ceased, or if any serious injury is inflicted on the animal, be killed before it recovers from the effects of the anaesthetic. In the experiments in which the initial operations are performed under anaesthetics but the animals are allowed to recover, the operations are required to be performed antiseptically, if the antiseptic precautions fail and suppuration occurs the animal must be killed. It is pointed out that experiments involving the removal of important organs, including operations of the brain, may be performed without giving rise to pain after the recovery from the operation, and that after the section of a part of the nervous system the resulting degenerative changes are painless. Exception is made in a few cases, such as experi-

ments which deal with the efficiency of antiseptics. Experiments performed without anaesthetics (which numbered 168,653) were mostly inoculations, but some were feeding experiments, or the administration of various substances by the mouth or by inhalation, or by external application, or the abstraction of blood by puncture or simple venesection. A certificate is required, not for the inoculation, or injections, or venesection, but to permit the subsequent course of the experiments, which lasts during the whole time from the administration of the drug or injection until the animal recovers from the effects, if any, or dies, or is killed—a period possibly extending for several days or weeks. To administer to an animal diphtheria toxin, or to induce such a disease as tuberculosis, though not accompanied by acute suffering, is held to be a proceeding calculated to give pain, and therefore such experiments come within the scope of the Act. It is noted that in a large number of the experiments performed the results were negative. The returns show that during 1924 the number of experiments performed by twelve licensees in the course of cancer investigations was 8,083, of these, 7,754 were almost all inoculations into mice or exposure of animals to radiations. A large number of the experiments, almost entirely simple inoculations and similar proceedings, were performed either on behalf of official bodies, with a view to the preservation of the public health, or directly for the diagnosis and treatment of disease. Several county councils and municipal corporations have their own laboratories in which bacteriological investigations are carried on, including the necessary tests on living animals, and many others have arrangements by which similar observations are made on their behalf in the laboratories of universities, colleges, and other institutions. A sewage farm is registered as a place in which experiments on living animals may be performed in order that the character of the effluent may be tested by its effects on the health of fish. 198 licensees performed over 43,000 experiments for Government departments, county councils, municipal corporations, or other public health authorities, 44 licensees performed over 76,000 experiments for the preparation and testing of antitoxic serums and vaccines and for the testing and standardizing of drugs. The net result is that the total number of experiments in 1924 was 177,815, being 43,032 more than in 1923. The Home Secretary, under whose control the Act is administered, has an advisory committee, consisting of Viscount Cave (chairman), Sir John Rose Bradford, Sir Archibald Garrod, Sir W. B. Hardy, Sir D'Arcy Power, Sir Seymour Shirley, and Sir Charters Symonds.

THE PREVENTION OF RABIES

HISTORICALLY rabies was one of the earliest specific diseases to be known and described—Aristotle, Virgil, Horace, and Plutarch all mention it, yet we still know very little of its cause. Indeed, in recent years comparatively few advances have been made on the work of Pasteur and Roux. New methods of vaccination have been produced, however, and of late there has been a tendency to attack the disease from its origin in the dog. Diagnosis of the disease in the dog is still of first importance for both prophylaxis and treatment. Clinically many pseudo-rabid syndromes exist in that animal which render an exact diagnosis difficult. Changes in the ganglia are not always evident, and subdural inoculation of rabbits is slow in yielding results. The most reliable test is still the demonstration of Negri bodies in the brain, although Moore¹ believes that these sometimes escape detection. Rabies can be kept under control by quarantine regulations—as in this country—or by canine inoculation such as is now being practised in many countries abroad, including the United States and Japan. A vaccine, developed largely in the latter country, which appeared to give excellent

results, has been previously referred to,² but recently Mohler (of the American Bureau of Animal Industry) has asserted that while the vaccine gave protection against two strains of street-runs, it was ineffective against a third. The duration of the protection conferred has not yet been definitely ascertained—the Japanese do not put it beyond a year. Accordingly Moore recommends that until more definite information is available reliance must be placed in early diagnosis and enforcement of a proper quarantine. If rabies does appear vaccination should be adopted in addition to the quarantine, but though strongly recommended in this connexion it must still be regarded as a supplementary measure. Where rabies is enzootic the vaccine already elaborated should give considerable protection to the community. An effective diagnosis after a person has been bitten by a supposedly rabid dog is of great importance. Many people suffer unnecessary mental agony through a mistaken belief that they have been bitten by a rabid dog when some other non-infectious disease has been the cause of the symptoms in the animal. This applies even to this country, from which rabies is at the moment absent. As we have pointed out many times, it is a mistake immediately to destroy the animal, for the opportunity of making a satisfactory diagnosis is thus frequently lost. It is desirable to keep the animal alive—under proper conditions of confinement and supervision, of course—until the presence or absence of the virus can be definitely ascertained. While the incubation period in dogs is variable, sometimes exceeding six months, it is only infectious within a comparatively short time of the development of actual symptoms. Accordingly every animal biting a human being in countries where the disease exists should be kept under close confinement for at least a fortnight. Panisset and Verge³ have recently formulated a useful set of rules for the procedure to be adopted at the end of the fortnight: if, during the interval, the dog dies from any cause, is killed, or disappears, antirabic treatment should be given, if the animal is alive and shows symptoms of rabies or symptoms simulating rabies, treatment should be given, if, however, it is ill but with symptoms not simulating rabies, the observation period should be prolonged, while if it is alive and well no treatment is necessary. This set of instructions does not, of course, invalidate the golden rule—when in doubt give the patient antirabic treatment.

SCIENTIFIC RESEARCH WORKERS AND INDUSTRY

THE British Science Guild published a report in 1919 reviewing the position of industrial research, and showing how far this country was behind Germany and the United States in providing for scientific training in industrial research. It was felt that the adequate supply of highly trained scientific workers and technologists was a matter of the greatest urgency, since upon it depended the prosperity and safety of the country and the development of the natural resources of the Empire. The supply of scientific workers has since been greatly increased, but it now appears that there is increasing difficulty in obtaining employment for them. The results of an inquiry made into the present position with regard to the supply of trained workers and their utilization in industry has been embodied in a report published by the British Science Guild, at 6, John Street, Adelphi W.C.2. Medical research workers are not included in this report, as their position, it was considered, called for separate inquiry. Comparison of the year 1923-24 with the year 1913-14 shows that the number of full time students in science at the British universities has increased by 60 per cent, while the number of bachelor degrees in science has more than trebled. During the same period the number of full time post-graduate students

¹ Cornell Veterinarian 19-5 xv, pp 217-226

² BRITISH MEDICAL JOURNAL, December 6th, 1924 p 1062.

³ *Per Gen Med Vet* March 1925

engaged in scientific research has increased to over four times the figure for 1913-14. The inquiries show further that there is considerable unemployment among recently trained scientific research workers, especially in the case of research chemists. It is concluded that, though the value of scientific research to industry is well recognized, the part that industry itself can play in maintaining an adequate supply of research workers and in promoting scientific research is not so clearly understood. The demand for these workers should come from industry, either directly by the provision of posts on the research staffs of the great industrial enterprises and the industrial research associations, or, indirectly, by financial assistance from industry for experimental research. It is suggested that research workers might well be maintained in university laboratories or in special research and experimental stations to work on specific problems under the direction of an expert committee, and further, that a permanent staff of research fellows might be maintained in a special building, with fully equipped laboratories, their services being available for industrial firms which would pay the necessary expenses, and require, subject to an arrangement for royalties, the results of the investigations as their sole property. Such an organization would supplement the activities of the existing industrial research associations. A strong recommendation is made that an expert committee should be formed as an integral part of the department of scientific and industrial research, or as a separate entity, to examine inventions and to arrange for the commercial trial of those which were passed by the committee as being probable of industrial value.

THE ROCKEFELLER FOUNDATION IN 1924

DR GEORGE E. VINCENT, the President of the Rockefeller Foundation, gives his usual attractive review of this organization "for the well-being of mankind throughout the world." Its activities, which are wide, especially in America, Europe, and China, are graphically shown in a map. The directions in which assistance has been given during the year are tabulated under nineteen heads, of which the present effort is concentrated on public health and medical education. Before granting help to any existing institution the conditions are carefully studied at first hand by a representative of the Foundation, and it is qualitative advance in some special line of scientific, administrative, or educational direction, and not quantitative expansion of routine activities, that is taken into account. Selection is obviously needed, for during the year no fewer than 622 formal applications for aid were refused. While emphasizing the great value of the work of the general practitioner, it is pointed out that he must meet new conditions and take part in some measure of team work in the use of laboratories so as to become a practitioner of preventive medicine—in fact, a health counsellor. The International Health Board's campaign against hookworm disease which grew out of the original Rockefeller Sanitary Commission (1909) has now been extended to fifty-two countries in six continents and twenty-nine islands. Until 1924, when there was an outbreak of yellow fever in Salvador (seventy-five cases with twenty-two deaths), there had not in recent years been any cases in Central America; there are no carriers of the virus of yellow fever, as in the case of malaria and enteric fever, a survivor becomes free from the germs and is immune, the disease, it is believed, is kept going by cases in young children, in whom it is usually mild and often not recognized as such, these cases serving to infect the mosquitos. In order to facilitate the spread of medical knowledge among workers in various parts of the world the Rockefeller Foundation has pledged itself to provide 350,000 dollars for ten years to found and

maintain an international journal for abstracts of the biological sciences. Another new departure in this special direction—namely, the bulletins dealing with *Methods and Problems of Medical Education*—was started in September, 1924 (vide *BRITISH MEDICAL JOURNAL*, 1924, ii, 859), they come out, not at any specified time, but when suitable material becomes available. During 1924 some form of fellowship stipend was granted by the Rockefeller Foundation to 864 graduates of promise and young officials selected with the advice of Governments and university departments of thirty-three different countries. This review, which is well illustrated, fills the reader's mind with sincere admiration for the principles, policies, and work of this great Foundation.

TREATMENT OF TUBERCULOSIS IN POOR LAW INSTITUTIONS

FOLLOWING the reception of a report by medical officers of the Ministry of Health on the institutional treatment of tuberculous patients by boards of guardians, the Minister of Health has addressed a circular (607), together with a covering letter (607A) to these boards emphasizing the desirability of closer co-operation between them and those local authorities which are concerned with this form of treatment. The Minister considers that it is advantageous to appoint tuberculosis officers as consultants on the staffs of Poor Law institutions. Co-operation between the dispensary and the Poor Law services is thus facilitated, and the guardians obtain the benefit of the clinical services of a specialist who in many cases will have a personal knowledge of the previous medical history of the patient, and be responsible, as a rule, for the patient's supervision after discharge from the infirmary. It appears that some patients in an early stage of the disease are admitted to infirmaries, whereas they might preferably be treated in a residential institution by the local authority under its tuberculosis scheme. The Minister points out that it is desirable, therefore, that the medical officers of Poor Law institutions should, by consultation with tuberculosis officers, obtain adequate knowledge of other residential accommodation for such patients. In the opinion of the Minister of Health the provision of new accommodation for the institutional treatment of tuberculosis is a matter for the county and county borough councils, and that where boards of guardians propose to extend such accommodation as they have, they should in the first instance ascertain the views of the county or county borough council as to the need for such additional provision, and as to whether such additional provision should not be made by the council. A copy of this circular has also been sent to county councils, county borough councils, and joint committees for tuberculosis in England.

By an Order of the Privy Council dated July 31st, Sir Charles S. Sherrington, O.M., G.B.E., Sc.D., President of the Royal Society, Wavenslete Professor of Physiology in the University of Oxford, is appointed a member of the Medical Research Council from September 30th next. The vacancy is caused by the retirement of Dr. Henry Head, F.R.S., who leaves the Council under the provisions of the Royal Charter governing the rotation of membership.

CANDIDATES for the M.R.C.P. London may be glad to have their attention specially called to the alteration in By-law 112 approved at the meeting of the College on July 30th, as reported in our issue of August 8th (p. 276). The age for examination and for conferment of the diploma has now been reduced from 25 to 23 years. It may also be noted that a committee of the College has been for some time engaged in revising the by-laws and regulations relating to the examination for the Membership.

THE VOLUNTARY HOSPITALS COMMISSION.

REPORT ON ADDITIONAL ACCOMMODATION REQUIRED

MR WHEATLEY, as Minister of Health, on April 22nd, 1924, requested the then existing Voluntary Hospitals Commission to inquire into and to report upon "the extent of the additional voluntary hospital accommodation required in England and Wales and the best means of providing and maintaining it." The report, which has been presented to his successor, Mr Neville Chamberlain, is a relatively short document of twenty-four paragraphs, supplemented by two important appendices.

The Commission directed its inquiry to a consideration of what extensions could be regarded as immediately necessary and capable of accomplishment within a reasonable period. Owing to war conditions the hospitals had not expanded with the growth of population, but the improvement during the last two years is noted as evidence of the vitality of the voluntary system, though it is added that a large proportion of this activity has necessarily been put to the provision of further accommodation for nurses, and that this has checked further provision for patients.

Local Voluntary Hospital Committees

A paper of questions was issued to all voluntary hospitals through the Local Voluntary Hospital Committees, which were asked to collate the results and make recommendations, after taking into account the other facilities in their areas for the institutional treatment of disease. The reports confirmed the wisdom of setting up these local bodies, which afford centres for co-operation for the activities of the voluntary hospitals. In addition to these reports the Commission had reports on selected areas from officers placed at its disposal by the Ministry of Health, and through the British Medical Association further reports were obtained from the medical practitioners in selected areas.

Fluctuations in Demand for Beds

The report discusses a series of topics which have been under consideration either as evidence of deficiency of hospital accommodation or as suggestions for its alleviation. A waiting list, while it shows that a hospital is not meeting the demands of the area which it serves, does not quite simply measure the deficiency. The numbers are subject to accidental and seasonal variation and may include cases that are simply maturing, and on the other hand not show cases which doctors would like to send in, but do not register, because they regard the application as hopeless. Lists not frequently revised include persons who have secured treatment elsewhere or no longer need it.

Poor Law Infirmaries

The suggestion of co-operation with Poor Law infirmaries has not received much favour, especially in areas where schemes of mass contribution to the voluntary hospital exist, but some committees reported that vacant Poor Law beds could be used to reduce the pressure on voluntary hospitals if they were transferred to the local health authorities. The Commission states that full use of Poor Law beds could not be secured under present conditions, but also says that the number of vacant beds in this class of institution is much smaller than is commonly supposed. It seems that there must be two types of hospital in congruence with two types of care needed. One case needs special diagnostic facilities and highly specialized methods, the other needs mainly skilled nursing which cannot be provided at home. Between the two will be a field in which either type of hospital may find scope for service. It is in practice difficult to restrict a hospital to chronic cases alone without unduly limiting the activity of the medical and nursing staffs.

Public Health Authorities

In relation to the shifting line of responsibility between the general hospital and the public health authority, in which the actual point now lies in surgical tuberculosis, the report indicates that, apart from difficulties arising in the needs of medical education, the hospitals might gravely impair their field of appeal to the public if they should insist on the health authority taking over all the cases in which it may become statutorily interested. The Commission regards this as a matter suitable for negotiation between the hospitals and the health authorities, both local and central.

Transfers from one Hospital to Another

The suggestion that patients might be transferred from hospitals that are full to others which have empty beds is regarded as on the whole impracticable, in view of the very definite idea patients have as to the hospital to which they are willing to go. The fact that cottage hospitals, as a class, have a high proportion of empty beds evokes the note that it is desirable to discourage the multiplication of small hospitals which in equipment and staff are at a disadvantage compared with larger hospitals. The suggestion of grouping the smaller hospitals with a neighbouring large hospital for co-operation is met by an expression of a doubt as to the power of the medical staffs of the larger hospitals to cope with the widened field of work.

Convalescent and Recovery Homes

While it is held that the effect of the convalescent home is rather to extend the total period of institutional treatment than lessen the stay in the main hospital, the recovery home, which is a branch hospital under the control of the main hospital, from which patients can be transferred but remain under the care of the same medical staff, is considered by some as the best form of future development. The removal of cases to the recovery home soon after their need of the special facilities of the main hospital was over would, it is argued, make possible a more extensive use of these facilities, while the new beds would be provided on a site less costly than extension at the main hospital. The system is still in the experimental stage and has not been tested on a large scale. This part of the report closes with a reference to the possibility of economy by the co-ordination of the activities of the hospitals within an area. Some of the relative facts will be found in the appendices to the report, but no specific recommendations are made by the Commission.

Estimate of the Additional Beds Needed

The Commission estimates the number of additional beds now needed to be 10,000 for England and Wales including London, and regards the burden of providing these beds within any reasonable period as altogether beyond the resources of the voluntary system. It regards the deficiency as due to the war, and is in agreement with Lord Curzon's Committee that some measure of State assistance is essential and can be given without prejudicing the voluntary principle by creating a demand for a continuing contribution towards the cost of maintenance.

Cost

Whereas the purpose of the former grant was to save existing institutions from the consequences of past misfortune, the object of the grant now proposed would be to secure the number of hospital beds needed for an area as a whole, and to ascertain where such beds can best be provided and at the lowest cost, due account being taken of accessibility and other relevant considerations. Schemes would therefore have to be prepared for an area as a whole, and in view of the expense of urban sites the presumption would be in favour of suburban annexes, apart

from special local conditions. The rapid changes which have taken place in hospital design make it desirable to give preference to buildings of a somewhat utilitarian and less permanent type.

The Commission, having given careful attention to the question of cost, and received special reports from Dr. Steel and Mr. Worsley on recent buildings, considers that as at June 1925, a reasonable figure for the cost of plain buildings of a utilitarian character would be £400 a bed, excluding the cost of site, furniture and equipment, and in considering the need of an L-shaped subsidy tiles this is its basal figure.

State Assistance for Capital Expenditure

The experience of the Commission in administering the recent grant of £500,000 has shown that the voluntary hospitals are with exceptions now solvent and would be able to raise the additional money needed for the maintenance of the 10,000 new beds but that they have no margin for new capital expenditure. The continuance of the present deficiency would react to the prejudice of the voluntary system and the Commission has come to the conclusion that a substantial measure of State assistance is essential.

It is recommended that if this L-shaped grant is given it should like the deficiency grant, be made a stimulus to the voluntary subscriber, by requiring an equivalent from local sources. To secure this the grant should be substantial and the Commission recommends a grant of 50 per cent of cost up to a maximum of £200 a bed, subject to the rest being raised locally or available from existing building funds. This would involve a total liability of £2,000,000 but the expenditure would be spread over a considerable period and the Commission seems to believe the alternative to be a series of demands for State assistance.

To administer such a grant would require the co-operation of local bodies such as the Local Voluntary Hospital Committees, but these would need to be widened and indeed reconstituted. In this reconstitution the Commission thinks that the direct representatives of the hospitals should not be in a majority. A central body would also be needed and the Commission states that should it be asked to undertake the duty it would in the first place request these committees to prepare schemes for their own future constitution.

The report concludes with acknowledgements of the services of the secretaries to the Commission, Mr. L. G. Broel, C.B. and Mr. P. Butler, and their staff.

Appendixes

Number of Additional Beds Needed.—The first appendix to the report sets out in detail for the hospitals of England and Wales outside London, the position as to the number of available beds, the waiting lists, and the number of additional beds which the hospitals have reported as needed. For a total population of 33,401,993, the number of available beds is approximately 36,703 in 674 hospitals—that is, for each 1,000 of population, 1.10 beds. The rates for the separate areas vary from 0.22 and 0.31 in Middlesex and Essex up to 2.46 in Bristol and 2.53 in Manchester. The waiting lists of 282 hospitals record numbers totalling 31,127. Of the hospitals, 191 report the need of additional beds totalling 10,614 when those whose needs do not exceed ten beds are omitted. The Commission is of opinion that this number may be reduced by about 20 per cent when the possibilities of local co-ordination have been explored. This leaves round 8,000 beds, which with the 2,000 needed for London gives the 10,000 which the Commission has taken as approximately the number of beds now needed for the whole of England and Wales.

Income and Expenditure.—The second appendix gives a comparative statement of the receipts and expenditure of the voluntary hospitals of Great Britain, and shows that while in 1920 only 44 per cent of the hospitals showed an excess of ordinary income over expenditure the position has steadily improved, and in 1923, 66 per cent showed a favourable balance. The total ordinary income has risen from £4,766,931 to £5,386,316, and there has been a slight decrease in expenditure.

REPORT OF THE MINISTRY OF HEALTH, 1924-25

We have already announced the publication of the annual Report of the Ministry of Health for 1924-25. It deals generally with the administrative work of the Ministry and is naturally of smaller interest to medical readers than the report of the Chief Medical Officer, of which an account has been given in three recent issues of the JOURNAL (July 11th p. 63, August 1st p. 216, August 8th, p. 261). In the following paragraphs some matters of more or less direct medical interest are selected for notice.

Health Officers

On March 31st 1925 out of a total of 1,612 council of county, metropolitan, and municipal boroughs, and urban and rural districts, 557 had whole-time medical officers of health. The corresponding figures for the previous year were 1,609 and 549. The remuneration of such whole-time officers was a subject of informal discussion in the course of the year between the department on the one hand and the British Medical Association and the Society of Medical Officers of Health on the other. As a result certain proposals were submitted by the department to the Association of Local Authorities, the London County Council, and the Metropolitan Boroughs Striding Joint Committee. These bodies did not at the time see their way to endorse the proposals, but the Association of Municipal Corporations reported to its constituents that it did not think the figures of remuneration unreasonable. In dealing with individual cases the Minister has decided to be guided by the proposals, and in cases of dispute between the British Medical Association and a local authority he will try to arrange a discussion between the parties.

National Health Insurance

Insurance Committees due to terminate their period of office on October 31st, 1924, are continued for two years after that date, owing to the appointment of the Royal Commission. As regards the scope of medical benefit 90 cases raising questions of scope came before Local Medical and Insurance Committees, who found themselves in agreement that only 7 of the 90 cases could be allowed, the other 83 being outside the benefit. This agreement made it unnecessary to refer any cases to the Minister.

The total cost of medical benefit in the financial year 1924-25 in England was £7,429,000, of which about £5,700,000 was paid to doctors, and the remainder spent on drugs and appliances, excepting certain small sums under special arrangements, and to approved medical institutions. In addition £200,500 was distributed in 1924 to rural practitioners for mileage, £10,000 was set aside for aiding unremunerative practices in sparsely populated areas, but all the necessary information had not been received to permit distribution by the end of the year.

Drugs and appliances supplied by chemists cost about £1,477,000, and drugs supplied by doctors in rural areas involved payments of about £180,000. Prescriptions dispensed by chemists numbered about 41,550,000, being an increase of 15 per cent on the previous year. The increased cost was about 17½ per cent.

In respect of unsatisfactory standard of service, money was withheld from 118 doctors and 24 chemists, the total being £1,764 9s. In one case £100 was withheld for failure to keep proper medical records. In another the same amount was withheld for failing to provide proper treatment. In this case removal from the medical list was considered. In six cases £50 was withheld, four in respect of treatment and two of records. The Minister received seven representations for removal of practitioners from the list, and three for removal of chemists. Two doctors were removed, one for failure to provide proper treatment, and the other for incorrect entries in his day-book with a view to increasing his remuneration, which was on an attendance basis. Two chemists were removed for inaccurate dispensing. Two inquiries were instituted by the Minister, one relating to a practitioner who had persistently failed to furnish reports on insured patients to the Regional Medical Officer, and the other relating to a chemist whose authorization to deal in dangerous drugs

had been withdrawn by the Home Office after conviction in the courts. The inquiries resulted in the removal of both names from the list. In twenty-four cases there were appeals against decisions of Insurance Committees regarding medical benefit administration. Of the total, eighteen were by doctors and six by insured persons and approved societies. Four of the doctors' appeals were allowed, ten dismissed, three withdrawn, and in one no formal decision was given. One appeal by a society was allowed, and five by insured persons were dismissed. Four doctors appealed against surcharges by Insurance Committees as recommended by Panel Committees, in respect of alleged excessive prescribing. One appeal was allowed, two were dismissed, and in one the surcharge was reduced. One appeal was lodged and was successful against disallowance of an anaesthetist's fee by a Panel Committee. A doctor's appeal was allowed against certain requirements by an Insurance Committee regarding notification of a change of surgical address.

Additional benefit schemes to the number of 6,612 were in force at the end of 1924. The great majority—5,358—were for cash increases only, and 1,104 were for cash and non-cash. Nearly £2300,000 was available per annum for dental benefit, and about £270,000 for hospitals and convalescent homes. The funds for dental benefit increased from £167,765 to £296,675 in the course of the year. The Approved Societies Regulations, 1924, made certain modifications in schemes for additional benefits, and societies have been circularized as to the material changes.

New South Wales.

CANCER RESEARCH FUND

DURING April of this year the New South Wales Cancer Research Fund was officially inaugurated at a meeting held at the Sydney Town Hall in the presence of the Governor-General and Lady Foster. The fund is in charge of a professional committee nominated by the Senate of the University of Sydney, of which Professor F. P. Sanders is the honorary secretary. Research work will be done under the control of this committee in the laboratories of the University. Funds to the amount of £5,000 and £2,500 have been given by the State and Federal Parliaments respectively. In all, up to the present, some £18,000 is in sight for this fund, and it is hoped that the objective of £50,000 will be attained.

UNIVERSITY OF SYDNEY

The tender of Messrs John Taylor and Company of Loughborough, for the erection of a cruciform of forty-nine bells, has been accepted by the Senate of the University of Sydney. The total estimated cost of the installation is £17,389. This cruciform is to be erected as a war memorial at the Sydney University. Dr. Walter Burfitt, a graduate of the University, has given it a sum of £1,000 for the foundation of a scholarship to be known as 'The Walter Burfitt Scholarship for the Advancement of the Study of Science.'

DEATH OF DR ERIC SINCLAIR

The State has sustained a great loss in the death of Dr Eric Sinclair, Inspector General of the Insane, a position he had held for the past twenty-seven years. He was born at Greenock in 1800, and studied medicine in the University of Glasgow. He landed in Sydney in 1881, and entered the Lunacy Department in the following year. He was appointed inspector-general in 1898. A strong man of dogged resolution, he gradually introduced reforms into the department until the asylums were transformed into true hospitals for the mentally afflicted, fully equipped and with a properly trained nursing staff. Through his efforts a pathological department, modelled on the lines of the laboratories at Claybury in England and in Edinburgh under the Scottish asylums, was established at the Sydney University. He was, in the main, responsible for the establishment of a chair of psychiatry at the Sydney University, of which Sir John Macpherson is the first professor. In 1918 the military authorities sought the services of a master

organizer and strong disciplinarian, and Sinclair was appointed principal medical officer to the Second Military District—a department which he organized successfully, and administered satisfactorily until the end of 1920, when he was transferred to the reserve. He was President of the Section of Neurology and Psychology at the Australasian Medical Congress held at Melbourne in 1908. In character a strong man, of highest ideals, gifted with foresight and imagination, of great pertinacity of purpose, and, withal, with the most gentle and lovable nature, he will be missed by all who knew him, the loss to the community is great.

India.

CALCUTTA SCHOOL OF TROPICAL MEDICINE AND HYGIENE

At the Calcutta School of Tropical Medicine and Hygiene during 1924 researches were made into the use of carbon tetrachloride in the treatment of hookworm disease, the standardization of pure oil of hydrocarbons with its esters, the economical working of mechanical water filters, and other subjects connected with public health. Further advances in the development of the school are desired, including the appointment of a whole-time helminthologist and of a research biochemist. The organization of a department of hematology is felt to be an urgent need, and a museum of tropical medicine and hygiene is also required to form part of a special institute of hygiene. The fourth annual report, which deals with 1924, illustrates the great expansion in the general work of the school which has occurred. The Pasteur Institute began its work in June, 1924, and by the end of the year 1,995 patients had attended, of whom 1,461 had then completed their treatment, while in the case of 422 no treatment had been found necessary. Full accounts of the work of the different departments of the school are included in the report, which is richly illustrated by photographs. Subscriptions to the amount of 124,685 rupees were received during the year, and the expenditure amounted to 120,989 rupees.

PARCEL BACTERIOLOGICAL LABORATORY, BOMBAY

Under the auspices of the Bombay Branch of the British Medical Association and the Grant College Medical Society, a conference was held early this year. Sir Leslie Wilson, the principal guest of the evening, was received by Lieut.-Colonel F. P. Macle, director of the laboratory. Lieut.-Colonel Macle summarized the progress of the laboratory during the past year, and said that the output of plague prophylactic during 1924 had been nearly one and a half million doses—an amount that had been only twice exceeded in the history of the laboratory. It was estimated that nearly two-thirds of the whole cost of staffing and running the laboratory would be recovered by the charge made for this prophylactic. The reduction in mortality due to Hoffman's vaccine appeared to be about 47 per cent. The laboratory was used by the municipal authorities for the diagnosis of plague in rats, and some share was taken in the educational and propaganda work relating to the epidemiology of plague, malarial febrile diseases, tuberculosis, milk supplies, rabies, and disease-carrying insects. A considerable amount of research had been undertaken in connexion with the plague prophylactic, with special reference to the improvement of its immunizing powers. It was hoped that important practical results would be obtained shortly. Lieut.-Colonel Macle appealed for help towards the establishment of a mobile laboratory and a school of tropical medicine at Pune, and Sir Leslie Wilson in his speech, promised to give any support that he could.

NEW MATERNITY HOSPITAL IN BOMBAY

It is proposed to construct and endow a maternity hospital with 120 beds, near the King Edward Memorial Hospital and the Medical College at Pune. The hospital will be known as the Narmada Wadia Maternity Hospital, and will be governed by trustees and a board, on which the Government and the municipality will be represented. Twenty thousand square yards of land will be acquired at

a cost of about 3 lakhs of rupees, and the building equipment will cost a further 7½ lakhs. An annual grant of 30,000 rupees will be made by the municipality, and a similar amount will be given by the Government towards the maintenance of the hospital. The balance of the money is being defrayed from a gift of 16 lakhs of rupees by Mr. N. M. Widra for the extension of medical relief in Bombay, conditional on sixty beds being reserved in the new hospital for women labourers of the textile mills, who will be treated free of charge.

England and Wales.

THE BIRMINGHAM LABORATORY OF MENTAL DISEASE

THE annual report of the Laboratory of the Joint Board of Research for Mental Diseases of the City and University of Birmingham for the year ending March 1925, states that the general work has been to develop lines of research upon the basis of endocrine functions. Special attention has been paid to the thyroid gland, numerous determinations of basal metabolism have been made and are shortly to be published. The investigation of the iodine content of thyroid glands has been transferred to Birmingham from the pathological laboratory of the Maudsley Hospital, in original method for the accurate quantitative estimation of the iodine has been devised, and has been applied in sixty instances. It has been found that there is a great variation in the iodine content— from 15 to 44 milligrams per gland. This corresponds fairly well with the results previously obtained as to the extreme limits, but the method is more accurate in respect of individual cases. An inquiry has also been conducted into the action of certain hypnotic drugs on animals to ascertain their physiological action and their effect upon the general health and well-being. A large amount of routine serological, bacteriological, and chemical work has been done for the clinical staff of the Rubery and Holmwood Hospitals. It has included the investigation of a few cases of typhoid fever which have occurred in each institution. In view of the probable association between chronic sepsis and disturbed endocrine function bacteriological work has occupied a large part of the time of the workers in the laboratory. The examination of the faeces in certain gastrointestinal cases has shown many varieties of organisms, streptococci were present in many instances, occasionally in pure culture, Friedländer's bacillus often occurred in groups of cases—for example, nine out of twenty in one ward, *B. cloacae* was found in a blood culture in one case on two successive occasions. Thus, it is considered, suggests that organisms usually considered non-pathogenic may multiply and cause disturbance in debilitated patients, such as are commonly met with in mental hospitals.

THE LONDON AMBULANCE SERVICE

The London County Council has recently published another pamphlet of "The London County Council and what it does for London." The new publication is on *The London Ambulance Service*, and for it Mr. Montagu Cox, Clerk of the Council, has written a foreword. The London County Council was authorized by the Metropolitan Ambulances Act, 1909, to establish a service. Previously accidents and sudden illness in the streets were dealt with by the police and though many improvements were introduced, it was shown in 1899 that 70 per cent of casualties reached the hospitals in unsuitable ways. Sir William Collins appears to have been responsible for the passing of the Act of 1909, and in 1914 the Council formed an independent ambulance system of its own. The pamphlet describes the functions of the service, its growth, and objects. The qualifications, pay, and duties of the staff are set forth. The number of calls was 12,000 in 1917 by 1924 it had risen to 31,000. A chapter on curious incidents cultivates the account of the excellent work of the service, and the occa-

sional allegation of delay between the occurrence of an accident and the arrival of an ambulance is duly explained. The average time taken to reach the place of call in 1924 was eight minutes.

THE MILK AND DAIRIES ACT, 1915

The Minister of Health has issued an Order, dated July 28th, 1925, formally appointing September 1st 1925 as the date of commencement so far as it is not already in operation, of the Milk and Dairies (Consolidation) Act 1915 (England and Wales). A covering letter (Circular 612) is issued with the Order. From this it appears that a new Order is contemplated under the provisions of the 1915 Act for the making and enforcement of Milk and Dairies Orders, which extend the list of purposes for which similar Orders can be made under the Contagious Diseases (Animals) Act, 1878. In the meantime the Orders of 1885, 1895, and 1899 and the regulations made by local authorities under Article 13 of the Order of 1885 remain in force. The letter goes on to state that under the General Act the duty of enforcing the stoppage of the supply of milk which is likely to cause tuberculosis is placed upon the council of the county or county borough in which the cows are kept, and any order made by such council will prohibit the sale of the affected milk in any area. Previously the power of stopping the supply has been given to the local authority, and the prohibition only applied to that area. After one year from the commencement of the General Act, local Act provisions will be repealed. The covering letter then reminds local authorities of their duties under the Tuberculosis Order of the Ministry of Agriculture and Fisheries, which comes into force on the same day as the Act of 1915, and of their increased powers for taking samples of milk. Although samples may only be taken in the men for which the officer acts, an authorized officer of one authority may, by notice, require the medical officer or other authorized officer of another authority to take samples of milk within his area, the expenses being defrayed by the authority requiring the samples. Where the warranty defence is pleaded by a purveyor of milk a sample from a corresponding milking must be taken in the course of transit or delivery to the purveyor, and if the owner of the cows so requests a further sample must be taken at the dairy at which the cows are kept. The covering letter concludes by drawing attention to the definition of the expression "dairy." From this it appears that the expression "does not include a shop from which milk is not supplied otherwise than in the properly closed and unopened receptacles in which it was delivered to the shop." The language is not pellucid, but it is possible to arrive at the meaning of this sentence.

TUBERCULOUS DAIRY WORKERS

The Minister of Health has issued additional regulations bearing on the transmission of tuberculosis by means of milk. Article 4 is that "No person who is aware that he is suffering from tuberculosis of the respiratory tract shall enter upon any employment or occupation in connection with a dairy which would involve the milking of cows, the treatment of milk, or the handling of vessels used for containing milk." The regulations are to be carried out by the local authority, which must be satisfied, on a report by its medical officer of health, that a person in the district suffering from respiratory tuberculosis and in an infectious state is engaged as aforesaid, in these circumstances it may issue a notice, signed by the clerk or medical officer of health, requiring discontinuance of such occupation. The person receiving the notice may appeal to a court of summary jurisdiction, which may make such order as may seem equitable to it, and may award costs. The court is to have power, with consent of the appellant, to direct his examination by a registered medical practitioner nominated by the court. Any person sustaining damage through the regulations and not being himself at fault may take action for compensation. In a covering circular it is explained that the new regulations remove restrictions imposed by certain provisions of the 1912 regulations upon action by local authorities and their officers in cases of tuberculosis notified by the 1912 regulations.

KING EDWARD'S HOSPITAL FUND FOR LONDON

The annual report of the King Edward's Hospital Fund for London for 1924 records that the year was the first since 1919 in which the voluntary hospitals of London received no assistance from exceptional distributions towards meeting their maintenance expenditure. The steady improvement observable during the intervening period was very marked at the close of 1922, when the statements of account showed that the net aggregate deficit had declined from £381,000 for 1920 to £175,000. The total receipts of the fund in 1924 amounted to £412,472, of which £112,240 came from the estate of the late Mr John Wells, £50,203 from the estate of the late Sir Thomas Sutherland, and £16,000 from the estate of the late Mr Samuel Lewis. The general receipts amounted to £214,342, towards which the League of Mercy, as in the previous year, contributed £14,500. The King, as patron of the fund, continued his annual subscription of £1,000, while the Queen, Queen Alexandra, and the Prince of Wales subscribed generously. Among other large subscriptions were £4,000 from the Drapers' Company, £1,050 from the Imperial Tobacco Company, and £1,000 from the Merchant Taylors' Company. The amount of ordinary distribution was £235,000, of which £233,000 went to grants to hospitals, including recovery and convalescent branches. Convalescent homes unattached to London hospitals received £2,000. As the voluntary hospitals are beginning to balance their expenditure the needs for extensions and improvements, postponed owing to the war, are being considered, including the recommendation of the special committee presided over by Sir William Collins that the Distribution Committee should take into account at the annual distribution the question whether the hospital provided sufficient bed accommodation for accidents and cases of sudden illness. It is suggested that no institution not equipped for the reception and treatment of serious cases of accident or illness should be returned on the list of institutions to which ambulance cases should in the first instance be taken. The Wells legacies were made the subject of special distribution, mainly in aid of schemes of extension and improvement, including the provision of more accident beds. By the end of the year grants amounting to £81,000 had been approved in aid of schemes providing for 301 beds, of which 53 were to be reserved for accident cases, at King's College Hospital 40 beds were opened during the year, including 16 reserved for accidents. During the last ten years £3,020,428 has been distributed by the fund amongst hospitals, convalescent homes, and consumption sanatoriums. In the twenty-eight years of the existence of the fund the grand total of £8,432,484 has been received, representing an average annual income of £301,160.

Scotland.

EDINBURGH HEALTH DEPARTMENT REPORT

The annual report for 1924 of Dr William Robertson, M.O.H. Edinburgh, has recently been published.

Population—The population of the city estimated to the middle of the year 1924 was 426,305 and the number of inhabited dwelling houses was 101,625 (an increase of 240, as compared with 1923). Of these no fewer than 40 per cent were of one and two apartments and these were inhabited by 37 per cent of the entire population. To this congestion are attributed many of the difficulties experienced in dealing with some of the most pressing health problems.

Deaths—The death rate for the city during 1924 was 14.8 per 1,000 as compared with a death rate for the whole of Scotland of 14.4 and one of 16.1 in Glasgow. The highest death rate occurred in the more crowded wards of the city, notably St Giles Ward with 17.8 per 1,000 and St Leonard's Ward with 17.7. In some of the suburban wards the death rates were only 10.6 and 11.1. In regard to the causes of death, the proportionate figures follow very closely those for the whole country, the leading causes being in order diseases of the circulatory system, cancer, pneumonia, cerebral haemorrhage, and tuberculosis.

Child Welfare—The child welfare work increased during the year both as regards visits paid by official health visitors and as regards the number of mothers who brought their infants for supervision to the centres. A suggestion was being considered to complete a comprehensive maternity and child welfare centre in

the Pleasance area, which would include accommodation for other child welfare activities in addition to clinics. During the past year four are lamps had been installed at the infectious diseases hospital in the annex for the treatment of surgical tuberculosis by artificial sunlight, and striking results had been obtained. Treatment of rickets and malnutrition by irradiation with mercury vapour lamps had also been tried.

Diphtheria—Gratifying results were obtained in an elaborate experiment conducted with a view to ascertaining the value of immunization of children against diphtheria. In all, twenty-six schools were taken in hand and 3,507 children were immunized without any untoward result. This encouraged the municipal authorities to undertake in future the immunization of children before attaining school age.

Other Epidemic Diseases—Towards the end of the year the city was invaded by an epidemic wave of measles and whooping cough. In order to discover the circumstances of those who required hospital treatment the Public Health Committee extended notification to the first cases of these diseases occurring in any house and two nurses trained in managing fevers were appointed visitors. A grant in aid of the Scottish Board of Health in the month of December 1,524 cases of measles were reported and 120 deaths and whooping cough for 85, chiefly among young children. The number of cases of scarlet fever during the year was 1,761, with 63 deaths. Only 27 cases of enteric fever were reported to the department and in 8 of these it was definitely ascertained that the disease had not been contracted in the city. Enteric fever appeared to be dying out. There were 720 cases of diphtheria with 73 deaths. This mortality rate of 10.1 per cent was higher than that recorded in any of the three preceding years. During the year 15 cases of cerebro spinal meningitis were reported with 11 deaths.

Tuberculosis—For the past three years the number of deaths from pulmonary tuberculosis had been increasing until, in 1924, it had reached 424. This rise could be accounted for in part by the present unsatisfactory housing conditions. During the year 799 cases of pulmonary tuberculosis were notified to the department, as compared with 692 and 762 in the preceding two years. The number of cases of non-pulmonary tuberculosis intimated to the department during the year was 455, as compared with 482 and 485 in the preceding two years.

Veneral Diseases—A total of 3,361 new patients suffering from venereal disease were reported for examination at the various centres (2,292 men and 1,569 women and children). 808 had required in-patient treatment, or 17.5 per cent. The number of attendances during 1924 was 106,456 as compared with 92,912 in the preceding year and the number of patients (3,861) in 1924 was a considerable increase on that in the preceding year (3,579). The great amount of bacteriological and serological work necessary was done in the clinical pathology department of the Royal Infirmary. The chief drugs used in the treatment of syphilis were salvarsan and its substitutes, some 30,000 injections had been given but treatment by preparations of bismuth gave very promising results in over a thousand cases so treated. During the year 1,712 patients were discharged from hospital, after passing the tests of cure.

Purity of Food Supply—Analyses were conducted of 468 statutory samples, an increase of 27 per cent. Of these 83 were certified by the city analyst as not being up to the standard, and 16 prosecutions were instituted against offenders. These proceedings were successful in every case. In addition to these 148 samples of sweet milk had been obtained at shops and railway stations for bacteriological examination by the veterinary department. Of these, 58 per cent conformed to the general bacterial standard laid down for Grade A milk, but only 33 per cent were up to its coliform standard as the bacterial standard for this milk was low, and as experience had proved that it could be easily maintained with an ample margin by any producer who exercised ordinary care in the collection and handling of milk, and in the cleansing of milk containers this result would not appear to be very satisfactory. The total approximate daily sale of all classes of milk was 22,704 gallons, which was equal to an average consumption of about half a pint per person a day. Progress had been made with the sale of the various grades of milk and the amounts of these sold daily were as follows: Certified "185 gallons," "Grade A (tuberculin tested)" 33 gallons, "pasteurized" 2181 gallons making a total of 2,449 gallons as against a daily consumption of non-graded milk amounting to 20,255 gallons.

WATER SUPPLY OF SCOTTISH TOWNS

An inquiry was opened on July 29th at Edinburgh into a series of Scottish Provisional Orders. Sir George Berry, LL.D., M.P., presided over the meeting of Commissioners. One of the chief subjects considered was the Perth Corporation Water Order. The water supply of Perth had hitherto been obtained from the river Tay by pumping, and has hitherto been found insufficient. The present provision was described by the promoters of the new scheme as one which kept the city of Perth living on the "verge of a precipice of disease," because the sewage of the city was discharged at a point only four hundred yards distant from the pumping station, and, as the river at this point was tidal, the sewage was at times carried by the tide past the entrances to the filters. It was stated that this state of matters tended to keep the typhoid rate of the town abnormally high, as

well as to produce a form of diarrhoea. It was now proposed to obtain a gravitation water supply from Loch Ordie, high in the hills in an uninhabited district, twenty miles from Perth, with a catchment area of nearly 4 500 acres, the scheme would supply four and a half million gallons of water a day, and would cost £300,000. The city of Aberdeen has also recently provided a new water supply and the works were last week visited by the Conference of the Institution of Water Engineers. Mr. George Mitchell, M Inst C.E., who presided, said that the city of Aberdeen, with a population of 160,000, was supplied with water drawn from the river Dee, twenty miles west of the city. The old works, completed in 1866, consisted of a twelve million gallon storage reservoir, with slow sand filters and a brick aqueduct, having a capacity of eight and a half million gallons a day. In 1916 the town council obtained powers to carry out a new scheme designed to supply an estimated future population of 240,000 with forty gallons a head a day. The new service reservoir at Cairnron is to contain seven million gallons, and has been constructed with a 24 in main supply pipe. The cost of the works carried out exceeded £900,000.

CENTRAL MIDWIVES BOARD FOR SCOTLAND

The examination of the Board, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, has just concluded. Out of 134 candidates who appeared for the examination, 121 passed. Of the successful candidates, 26 were trained at the Royal Maternity, 38 at the Royal Maternity Hospital, Maternity Hospital Aberdeen, 9 at the Maternity Hospital, Dundee, 15 at the Queen Victoria Jubilee Institute, Edinburgh, and the remainder at various recognized institutions.

Ireland.

NOTICES IN THE PUBLIC PRESS

At a meeting of the Council of the Royal College of Surgeons in Ireland on July 16th the following resolution was adopted, and directed to be sent to the Fellows and Licentiates of the College:

The Council of the Royal College of Surgeons in Ireland having discussed the question of the propriety of certain notices which appeared in the public press during the recent visit of the American doctors, decided not to take any special action in the matter trusting that the Fellows and Licentiates of the College will do all in their power to prevent the publication of such notices which are not in accord with the reserve prevailing in this country as to such matters.

Correspondence.

THE USES OF COELIOSCOPY

SIR,—I think Mr. Rendle Short (August 8th, p. 254) is to be congratulated on having drawn the attention of the profession to a method of examination of the abdomen which appears to have attracted little attention, although it was described fully by Otto Steiner, of Georgia, U.S.A. (*Surg., Gynecol. and Obstet.*, vol. XXXIII, 1924, pp. 266 and 575), who quotes Kelling (*Munch. med. Woch.*, 1902, No. 1, p. 21) and Jacobaeus (*ibid.*, 1910, No. 40, p. 2090).

I have been working at the same method of examination for the past eighteen months, in an endeavour to find the form of instrument best suited for the purpose. The principle adopted by Steiner is an instrument like a cystoscope, that of Mr. Rendle Short is, I gather, a cystoscope. I imagine there might be difficulties with an instrument with an optical system owing to blood or other substances getting on the lens of the telescope. I have had a direct vision instrument made for me by Messrs. Down Bros. which is simply a sigmoidoscope slightly modified, with a lamp at the end of the cannula. It is introduced under local anaesthesia through an incision three-quarters of an inch long in the peritoneum, para-medial, just below the umbilicus, with an obturator in place. The latter is withdrawn the skin edges clipped

with Poirier's forceps to keep the opening airtight, and the abdominal cavity inflated with air filtered through a glass tube filled with sterilized cotton wool. The biliary leads are enclosed in a sterile tube of linen. The further steps of the examination are conducted exactly as described by Mr. Rendle Short, the difference is that objects are viewed by direct vision and seen their natural size, the field of vision is of course much more limited. Air distension of the abdomen appears to cause little or no discomfort, and is then carried out under general anaesthesia. The anaesthetist has told me that the breathing and colour improve as soon as air is pumped in. As an example of its use I may describe a case I operated on to-day.

The radiographer had reported a fibrous defect at the pylorus with five hour retention. With the direct vision coelioscope the anterior surface of the stomach and the first part of the duodenum could be clearly seen and were apparently normal. A distended gall bladder with walls mottled red and yellow in patches could also be clearly seen. On reversing the instrument the bulbous tip of the appendix was seen for about an inch protruding from under the caecum. Laparotomy was immediately performed. The gall bladder with thickened oedematous walls was removed together with a thickened knicked appendix. No abnormality was found in the stomach.

I should like to endorse all that Mr. Rendle Short says in his paper, especially would I like to bear out the remarks in his last paragraph. Nor do I think he is unduly enthusiastic as to the scope and uses of coelioscopy. A criticism levelled at me by a colleague was that if an incision has to be made in the abdominal wall, the surgeon may as well make one of five inches and see and feel everything, as make an inch incision. This is an obvious fallacy. In the first place, one does not see everything through a five inch incision, although one may feel everything. In the second place, it can hardly be as good for the patient, and I do not think that even to-day we can tell a patient that a laparotomy carries no risk. At the present time I know of two cases where, through the premature removal of the deep silk worm gut stitches, the wound has burst open in the entire absence of sepsis or a laceration, and where the wound was carefully closed in layers.

As a further example I may mention two cases of carcinoma of the colon where I was able to see secondary deposits in the liver. These patients were able to leave hospital in three days. It is quite certain, as Mr. Rendle Short states, that patients with malignant disease of the abdomen do die in some cases within two or three weeks after a simple laparotomy.

In conclusion, I may say that about three months ago I submitted a paper entitled "A preliminary note on a method of examination of the abdomen by air inflation or abdominoscopy" to a leading journal, and gave an account of certain cases in which I had used the method I have described. Possibly on account of the hybrid word "abdominoscopy," which, by the way, is that used by Steiner, it was returned to me with the comment that "As the method has been before the profession for the past twenty years or more, what is wanted is a record of actual clinical experience with it, in what class of case it has proved useful and so forth." It may be my limited reading of medical literature that is at fault, but the only references to the method I have come across are those here quoted above and Mr. Rendle Short's brief article in the *Journal* of to-day.—I am, etc.,

Cardiff Aug 8th

J. W. GEARY GRANT

BRITISH SOCIAL HYGIENE COUNCIL

SIR—In your issue of July 11th (p. 88) Mr. C. J. Bond, C.M.G., F.R.C.S., makes an eloquent appeal for a body which is to be known as the British Social Hygiene Council, and whose aim he states will be to provide for the adolescent population not only "sound instruction and wise advice in the principles which underlie the right living of the sex life," but also "instruction and guidance in healthy and right living in every department of life, individual and communal." This council proposes, in short, to do what not only parents, but also "churches and other religious bodies have so far failed" adequately to do.

These are praiseworthy aims, but, alas! is not a profound

fillicy involved at the very outset? Before we can teach anything we should at least have reached among ourselves some general agreement as to what is to be taught. Yet, in the present instance, views on the very "principles" themselves are notoriously discordant. Thus, regarding the particular topic of the sex life itself, we have diametrically opposed positions, as of those who consider continence and self-control the primary essential—indeed, *a sine qua non*—and those, on the other hand, who pin their faith on "birth control" apparatus, the V D clinic, *et hoc genus omne*.

And similarly with all views of "right living" or "citizenship in the wider sense", the tragedy of our day is precisely that there already exist countless philanthropic organizations which desire to enlighten us on these matters—all equally well intentioned, but all fundamentally at loggerheads regarding the very elements of their subject. I see that Mr. Bond foreshadows some kind of co-operation between his council and the State. Can it possibly be that when he has got his council ready and a full membership, he expects to be vouchsafed enlightenment regarding the "principles of mental and moral health" from some Government department? If this be so, then he must not be surprised if quite a number of plain but level-headed people, who have done no more than use their eyes during these years of world-wide Prussianism and Socialism, decline to follow him further. But if it is not so, then will Mr. Bond, before he, so to speak, "sends the hat round" and invites our suffrages for his new venture, grant us a little more information? What are the sources of those principles which he proposes to instil into the adolescent mind? He acknowledges that "at present teachers are not available." Who, then, are going to teach the teachers, and—above all—what are they going to teach them to teach?—I am, etc.,

Edinburgh, July 13th

ARTHUR J. BROOK

CANCER BURIAL OR CREMATION?

Sir,—Were Dr. Brodribb not better advised (see his letter on the question in your issue of August 8th, p. 271), did he advocate universal cremation of all animal remains? This would cover all undiagnosed cases of malignant disease, in the lower animals as well as in man. His Dr. Brodribb may reason for believing that micro-organisms behave alike in a living body and under conditions outside of a living body, that deep has the same effect on micro-organisms as has shallow burial, or that whether the soil be dry or water-logged and the distance to be traversed before water is reached, be factors which have nothing to do with the problem? Are not the micro-organisms contained in the excretions, dejecta, and discharges of living bodies likely to be more potent than those contained in dead bodies?

Is the rural population of these islands so dense as it was in 1685? Is the incidence of malignant disease the same in rural as it is in urban regions? and is not the modern water-borne system of urban sewerage an entirely new device since 1685? We talk about modern foodstuffs lacking certain essential elements (vitamins, etc.), does not our soil suffer from kindred deficiencies? "Dust to dust, ashes to ashes" appears to suggest that Nature expects the return of what she has given on loan. The late Dr. Vivian Poore wrote most convincingly on this theme "Nature is the best of physicians and the wisest of surgeons." Ancient civilizations which suddenly become urban and predominantly industrial upset the balance of nature, is it wise to upset the balance of nature? In the matter of preventive measures against malignant disease we have a multitude of counsellors whose respective counsels are mutually at variance. For example, what school, if either, is right—that which advocates raw, or undercooked, food and drink, or that which advocates food and drink sterilized by cooking?

The suggestion may be a carrying of coals to Newcastle, for no man can keep pace with all of the views put forward in the medical press, but the sophistication of modern foodstuffs has its complement in the modern urban system of sanitation—in that part of it which is effected by means of water-closets. It is widely believed that the

primary focus of much invasion by malignant disease is to be found in the gut, most victims of the invasion use private and public water closets, and must often deposit therein the parasite of malignant disease (if there be one, as seems to be now demonstrated). We know how frequently splashing occurs, and the inference is obvious. This suggestion is one of wide application to sumptuous utensils. For example, for generations old-fashioned country people have attributed cases of epithelioma of the lips or of the mouth, not to the taking of tobacco, but to the victims having smoked other people's pipes.

I hazard the guess that were all people persuaded, as a matter of routine, always to flush out water-closets before using them, we should have a more effective weapon with which to combat malignant disease than could be afforded by cremation, *pace* the fact that cremation is by far the most effective method of disposing of dead bodies.

But the agnostic attitude is necessary towards the cancer problem—I am, etc.,

London, S W 1 Aug 9th

M. CAMERON-BLAIR

MEDICAL OFFICERS AND CONSULTING FEES

Sir,—As inquiries have reached me asking reasons for the withdrawal of the Derby motion at the Bath Representative Meeting, may I be permitted to state, for the information of those interested who were not present at the meeting, that in view of the latest announcement by the Council in the matter (para 245, p. 279 of the SUPPLEMENT dated June 27th) it was considered that the motion was no longer necessary (SUPPLEMENT, August 1st, p. 59)—I am, etc.,

P. HEFFERNAN,

Buxton Aug 8th

Representative Derby Division

ULTRA-VIOLET LIGHT

Sir,—We notice in your issue of June 20th (p. 1152) a letter by Dr. Blakiston of Birmingham, wherein he states that the cost of running a tungsten arc lamp is £300 per 1,000 hours worked, whereas the cost of running a quartz lamp for the same period is £2 10s.

We would like to point out that Dr. Blakiston is entirely wrong in these statements. The cost of running a tungsten arc lamp for 1,000 hours is £31 5s., which is approximately one tenth of the amount quoted by Dr. Blakiston.

Dr. Blakiston states that the tungsten arc lamp is admittedly a good one, but claims the same for the quartz lamp. We can only agree with Dr. Blakiston if he will state what period of the life of the lamp he refers to the ultra-violet radiations from a quartz lamp begin to fall off from the first day it is put into use, and after running for 800 hours the lamp is practically valueless from the therapeutic ultra-violet ray point of view. A new burner would have to be provided at a cost of about £12—I am, etc.,

F. W. READ,

Director Medical Supply Association Ltd

London W C 1 Aug 5th

The Services

DEATHS IN THE SERVICES

Inspector General Leonard Henry Kellett R.N. (ret.) died at Bedford on August 3rd aged 75. He was educated at Dublin in the school of the Irish College of Surgeons, and took the L.R.C.S.I. in 1866 and the L.R.Q.C.P. in 1867. He entered the Navy shortly afterwards and retired in January 1909. He served in the Sudan with the Royal Marine Battalion in 1884-85 and was present in the actions at Hashim and the attack on Sir John McNeill's zariba at Tofrek in March 1885 and at the capture of Tamai on April 3rd 1885, receiving the Egyptian medal with a clasp for Tofrek and the Khedive's bronze star.

Major Albert Edward Peel McConnell M.C., R.A.M.C. (T.F.) died in London on June 9th aged 57. He was the son of the late Mr. J. H. McConnell of County Antrim and was educated at Campbell College Belfast and at Edinburgh where he graduated M.B. and Ch.B. in 1913. He took a commission as lieutenant in the 3rd South Midland (Birmingham) Field Ambulance on September 5th 1914 became captain in 1915, acting major in March 1918 and major in the R.A.M.C. (T.F.) in 1920. He served with the unit in France and Italy throughout the war was twice mentioned in dispatches in 1917 received the Military Cross on October 18th 1917 and the Italian medal for valor in 1918. At the time of his death he was in practice at Stoke Newington.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

BEFORE Parliament adjourned for the long recess the Royal Assent was signified to the Therapeutic Substances Act, Diseases of Animals Act, Summer Time Act, Widows' Orphans', and Old Age Contributory Pensions Act, Public Health Act, Dangerous Drugs Act, Surrey County Council Act, and several Acts confirming Provisional Orders of the Ministry of Health. The Dangerous Drugs Act had been mentioned by the Prime Minister as one which must stand over until the House reassembled in November, but in the days preceding the adjournment the Home Secretary secured its passage through the House of Commons without debate. Other statutes already passed include the Mental Deficiency (Amendment) Act, the Town Planning Act, and the Town Planning (Scotland) Act. The question concerning the inspection of nursing homes, with regard to which Dr. Fennell had entered an objection to the Surrey County Council Bill, was not further mentioned.

The second reading of the Bethlehem Hospital Bill is set down for November 16th in the House of Commons, and the report and third reading of the Public Health (Scotland) Bill for the following day. This latter bill is concerned with the supply of insulin by Scottish public health authorities.

The Diseases of Animals Act provides compensation for the slaughter of animals condemned as tuberculous, if condemned before dispatch to the butcher. It is passed to facilitate the working of the Milk and Dairies Act, which was passed in 1914, and is to be enforced from September 1st. By the Summer Time Act the need for annual legislation to continue summer time is avoided and the period standardized. During the debates on this Act the House was impressed by the reading of a letter from the British Medical Association, declaring that medical opinion favoured it. The Dangerous Drugs Act carries out the recent Geneva Opium Convention, and adds several to the list of dangerous drugs. The Contributory Pensions Act is expected to remove a large class of persons from dependence on the Poor Law, and is thus a step to the general reform of the Poor Law, which the Minister of Health, Mr. Neville Chamberlain, may propose next session. A Rating and Valuation Bill, now before the House of Commons, is another step towards that end. During the debates on the Contributory Pensions Act Sir Robert Horne suggested that the new charges it made on employers and employed should be offset by reducing National Health Insurance contributions, and with them the future surpluses available for additional benefits. The Minister of Health rejected the suggestion. Answers to inquiries concerning the additional benefits to be provided under the National Health Insurance Acts, and about suggested amendments in those Acts, have invariably been deferred till the Royal Commission shall have reported. This it is expected to do about the end of this year.

There has been no debate on the Ministry of Health estimates this session, and the Minister has been largely occupied with the Contributory Pensions Act and the Rating and Valuation Bill. Housing, however, is being pressed forward. Regulations have been issued to ensure greater care in the handling and display of meat for sale, and to reduce the use of preservatives in foods. The Ministry proposes to give more general powers to local authorities to deal with tuberculous cases. Other health reforms to which it has attended include co-ordination of hospital services and amendments to the Midwives Act and the Children's Act. A scheme is in preparation for dealing with miners' nystagmus, but the Government has postponed the general measure codifying the Factory Acts, which had been prepared by the Home Office.

The Medical Committee of the House of Commons has been active throughout the session, and its opinions have carried weight with the Government. The Births and Deaths Registration Bill promoted by Dr Fremantle, after consultation with the Committee, did not succeed, but evoked a promise from the Government that the law of registration would be reconsidered with a view to legislation. A number of professional deputations have conferred with the Medical Committee, which has drawn the attention of the Government to certain grievances, particularly those of the R A M C, which the Cabinet has lately considered and hopes to alleviate. A scheme of bettering the conditions of the R A M C is, indeed, understood to await Treasury sanction. Certain members of the Medical Committee have undertaken an independent and unofficial investigation of the Spahlinger serums and vaccines.

Lay members of the House have shown increased interest in medical matters. Labour members have been most concerned with small pox and vaccination. There have been inquiries also about the medical services in India and in the tropical colonies. There have also been frequent allusions to health in mines and factories and the Home Secretary has recognized the desir-

ability of appointing more factory inspectors. The Medical Committee of the House in view of the forthcoming Factory Bill, has gone into the claims of certifying factory surgeons.

The Ministry of Health has not been the target of many denunciations for expenditure. In a debate on national expenditure on the day the House rose the Chancellor of the Exchequer referred to it. He said that it would be impossible greatly to reduce expenditure unless Parliament were prepared to contemplate a less scientific administration. These social services were intimately interwoven with the life of the people, and could not be drastically cut down.

Parliament has continued its financial support to the universities and to medical and scientific research, and the House has been informed that the recent advances in cancer research have been made under the auspices of the Medical Research Council. Lord Midhurst, in the House of Lords, has mentioned progress in the investigations under the same body into the problem of filter pressing viruses. There is strong hope that medical and scientific research will be further encouraged through the recent establishment of the Civil Research Committee.

Before the House rose the Select Committee on the General Nursing Council prepared a draft report. The committee was of opinion that the present syllabus of training for nurses should stand but should not be made compulsory, and that no lower alternative syllabus should be issued. It is also of opinion that election to the general places in the General Nursing Council should be open, without regard to the rank of the candidates.

Spahlinger Treatment—Lieut Colonel the Hon G F Stray (Parliamentary Secretary Ministry of Pensions) stated in answer to a question on July 28th that a few cases of pulmonary tuberculosis had been sent to sanatoriums in Switzerland by the Ministry. The cases selected were those in which the department was satisfied on the advice of its experts in tuberculosis that treatment abroad was essential and that equal good results could not be expected from the facilities available in this country. He was informed that the Spahlinger treatment had in fact been given in certain cases as an incident of their sanatorium treatment, but the resulting evidence as to the value of the treatment was not in the opinion of his medical advisers justifying the payment of patients at the public expense expressly for this form of treatment.

Salaries of Sanitary Inspectors—On the 13th Mr. Deville Chamberlain told Colonel Dyer that he was aware that in some instances local authorities proposed to appoint sanitary inspectors, but it was his picture that the approval was sought for the appointment of a sanitary inspector to be endeavour to secure that the salary paid was sufficient to attract efficient service. The circumstances of each case were to be taken into consideration in respect of size population and character of the district. It was not practicable to prescribe a uniform salary, but it would not be to the appointment of a sanitary inspector as a condition of approval.

Illness in Maternity Home - The Minister of Health was asked by Mr. Vincent about the maternity home of the Wandsworth Borough Council. He said that during the past seventeen months there had been a great deal of suffering from abscesses of the breasts. He said that the eyes of mothers made by patients and public bodies as to the complaints had been made by patients and public bodies as to the complaints had been proper treatment and that the eyes of mothers had been dispensed with except the matter was not all the staff had been wages as usual and, in view of the fact that he would institute an inquiry into the matter. Sir Kim Wood replied that the answer to the first part of the question was in the affirmative, and to the third part in the negative. The Minister of Health had for some months been aware of the special report of the Minister of Health had for question, but reported skilled inquiry had been referred to in the to elicit the cause of this unusual condition. He was up to the present, failed the borough council which had made every effort to grapple with the problem, had decided to close the home temporarily, and to give notice to the staff. The Minister of Health was suggesting to the council that a conference should be held locally at which his department would be represented in order to discuss future arrangements.

Miner's Dystagmus.—In the debate on the Dep^t of Mines vote several references were made to miner's dystagmus. Colonel Lane Fox, Parliamentary Secretary for Mines, said that the subject was receiving very considerable attention and research was constantly going on. A scheme was now being elaborated between the Home Office and the Mines Department, which he hoped would shortly be put into operation.

Medical Attendance on Wives of Naval Officers.—In reply to Mr Harrison, Mr. Dawson (Financial Secretary of the Admiralty) said that in view of the urgent need for economy it was impossible to arrange for the extension to the wives of naval officers generally of the privilege of free medical advice and treatment. The wives of a few naval officers serving in shore establishments might be attended free of charge by the naval medical officer of the establishment, provided his duties permitted.

Pensioners Ministry—In reply to Mr Robiason Major Tryon (Minister of Pensions) said he was not aware of any complaints by patients at Beckett Park Hospital, Leeds about the food supplied. The medical officer in charge of a case was authorized to prescribe

butter when necessary. The Minister added that he was not prepared to authorize in this hospital, any change in the general scheme of diet which had been adopted on medical advice for all the hospitals of the Pensions Ministry. The Minister of Pensions informed Sir Arthur Holbrook on August 7th that in any case where an officer in receipt of conditional award was considered by the medical officer in charge of the hospital to be likely at the conclusion of his treatment to be in a materially more disabled condition than was represented by his current award the patient was boarded before discharge and a provisional award suitable to his condition made.

Diet in Mental Hospitals.—Sir Kingsley Wood, answering for the Minister of Health, informed Mr. W. Baker that since the publication of the report of the Departmental Committee on Dietaries in Mental Hospitals the breakfast and tea meals had been considerably varied. A weekly allowance of 2s 6d was made to each 'Service' mental patient for additional comforts.

Cost of Medical Research.—Answering Mr. Duckworth, on August 7th Mr. Guinness (Financial Secretary to the Treasury) said the provision made in the Scientific Investigation Vote, 1925-26 in aid of the expenses of the Medical Research Council was £135,000. The grants in previous years had been

1924-25	£110,000	1921-22	£130,000
1923-24	£130,000	1920-21	£125,000
1922-23	£130,000	1919-20	£148,500

In addition certain inquiries were from time to time carried out by or on behalf of the Ministry of Health, the Scottish Board of Health, and the Service Departments. The whole cost of these inquiries was relatively small.

Financing Medical Benefit.—In reply to Sir Godfrey Collins on August 7th Mr. Neville Chamberlain said the National Health Insurance (Cost of Medical Benefit) Act 1924 provided that for the purpose of providing part of the additional cost of medical benefit for the years 1924, 1925 and 1926 certain sums were to be paid in those three years out of moneys in the Central Fund representing sums carried to that fund in respect of unclaimed contributions. The financial provision thus made involved the application of the whole of the estimated balance of unclaimed contributions at December 31st 1923 after allowing for the amounts estimated to be required for arrears grants. There was, therefore, no balance available to be allocated.

Nurses and Trade Union.—Sir Kingsley Wood told Mr. Gerald Hurst that so far as the Minister of Health was aware the guardians of the Stepney Union were not exceeding their powers when insisting as a condition of employment that candidates for the post of hospital matron should be members of a trade union. He could not interfere.

Picaine.—The Home Secretary, Sir William Jonsson Hicks said on August 6th that he was not aware of any discovery by Dr. A. J. Copeland of a new anaesthetic which would serve as an alternative to cocaine. Dr. Copeland had recently investigated the properties and effects of picaine a cocaine substitute prepared by German chemists. A caution regarding the supply and use of the drug had been issued through the pharmaceutical press.

Birth Control Instruction.—The Minister of Health said on August 6th that after very careful consideration he had decided that it was impossible to make any change in the instructions issued by the Ministry of Health to maternity centres for their guidance in dealing with the question of birth control.

Veneral Disease.—Answering Captain Wedgwood Benn Sir Kingsley Wood gave the following statistics of reported cases of venereal disease and total attendances at clinics during the years 1919 to 1924. The number of cases dealt with for the first time at treatment centres in England and Wales and found to be suffering from venereal disease was as follows: 1919 82,797; 1920 85,531; 1921 66,820; 1922 56,347; 1923 55,945; 1924 54,380. The total attendances at the centres were as follows: 1919 1,002,791; 1920 1,488,514; 1921 1,612,592; 1922 1,560,568; 1923 1,605,617; 1924, 1,645,415. Notification of these diseases was not compulsory.

Notes in Brief

Mr. Godfrey Locker-Lumpkin informed Dr. Watts that in view of the International Labour Congresses there was no necessity for the Home Office to be represented at the Fourth International Medical Congress of Industrial Accidents and Diseases to be held at Amsterdam in September.

The Government is not prepared to intervene in support of the claim of the British Red Crescent Society to be allowed to supply the Rifles with medical stores.

The Minister of Health is causing inquiries to be made into allegations that rashes, swollen arms and fever followed revaccination of children at Washwood Heath near Birmingham in June.

Austria, Czecho-Slovakia, Poland and Sweden have ratified the Convention of 1921 on the use of lead in painting buildings and have taken steps to give effect to it.

The Home Secretary declined to make any statement on death certification, as the whole subject is under consideration.

The veterinary inspection by local authorities of dairy herds in Scotland does not include systematic tuberculin testing.

In December 1923 921,127 persons in Great Britain were in receipt of old age pensions. In December 1924 the total was 937,160.

Obituary

GEORGE KENNEDY SMILEY, OBE, M.B., B.Ch.,
B.A.O. R.U.I.,

Regional Medical Officer for Manchester

WE announce with regret the death of Dr. George Kennedy Smiley, on August 2nd. Dr. Smiley received his medical education at Queen's University, Belfast, and Dublin, graduating M.B., B.Ch., B.A.O., R.U.I. in 1897. He was well known as a Rugby half-back. After graduating he spent a year at sea, he then held an assistantship in the South of England, and later studied in London as a general practitioner. He took an active interest in ophthalmology, and was honorary surgeon to the London-derry Eye, Ear, and Throat Hospital. On his marriage in 1906 he settled in England, starting general practice in Derby. Here he became actively interested in the work of the British Medical Association, he joined the Derby Division Executive Committee in 1912, and from 1913 to 1920 was honorary secretary of the Derby Division, and a representative from 1913 to 1917. In 1919 and 1920 he was a member of the Council of the Association, as one of the four representatives of the East Midland Branch. In the controversy regarding the National Health Insurance Act Dr. Smiley took a leading part in his own Division, and, when the profession agreed to take part in its administration, he became the secretary of the Derby Local Medical Committee, and later of the Panel Committee, and a member of the Derby Insurance Committee. In 1916 he was appointed chairman of the Medical Benefit Subcommittee, which position he held for two years, and, in 1918, he was elected chairman of the Insurance Committee. During the war he held the post of medical officer in charge of the Military Hospital at Derby, and after the armistice was awarded the OBE. He was also secretary of the Derby Local Medical War Committee. In 1919 he contracted acute sepsis of the left hand, followed by an illness lasting many months. When the Ministry of Health appointed its regional medical staff in 1920, Dr. Smiley was placed in charge of the Manchester area, where he quickly gained popularity with all his colleagues. Early in 1924 serious abdominal signs developed, and, though relieved by a palliative operation, a fatal issue ensued after fifteen months' illness.

Dr. BRODIE CRICKSHANK of Nairn died there on August 5th, aged 78. He was born at Montrose and educated at Aberdeen, where he graduated M.A. in 1856, M.B. and C.M., with first-class honours, in 1869, and M.D. in 1877. After filling the posts of resident surgeon at Aberdeen Royal Infirmary, and assistant physician at Perth District Asylum, he entered the army as assistant surgeon in April 1871, and served in the 80th Foot now the second battalion of the South Staffordshire Regiment. He resigned his commission in 1877, and soon after went into practice at Nairn where he held the appointments of provincial medical officer of Aulderin and Candor, consulting medical officer to the Town and County Hospital and medical officer under the Education Act. He was representative of the Banff, Inver, and Nairn Division of the British Medical Association for many years, and president of the Northern Counties of Scotland Branch in 1912. On December 13th, 1919 (p. 794), we announced the presentation to him of an illuminated address of congratulation on the attainment of his jubilee as a member of the medical profession.

Dr. FREDERIC VICTOR ELKINGTON of Fenny Compton, Warwickshire, who died on June 26th at the age of 61 received his medical education at Edinburgh University and St. Bartholomew's Hospital, and obtained the diplomas of L.R.C.P., L.R.C.S. Edin., and L.R.F.P.S. Glasg. in 1896. He was medical officer and public vaccinator for the Burton Bassett district of the Southern Union and lecturer and examiner to the St. John Ambulance Association and the Red Cross Society. He was a member of the British Medical Association and published an article

THE ninth Swiss Congress of Dermatology and Venereology was held at Zurich on July 4th and 5th under the presidency of Professor Bruno Bloch, when the following papers among others were read: Syphilis of the nervous system and its treatment, by Professor Dind of Lausanne, Electrolysis for hypertrichosis in women, by Professor Du Bois of Geneva, Erythrodermia and icterus after injections of acetylarsan, by Dr. Lussener of Lausanne.

An advanced course of pathological anatomy will be held under the supervision of Professor G. Roussy, in Paris, from October 5th to 30th, and will include lectures and practical work. The fee for the course is 150 francs, and the number of places is limited. Inquiries should be addressed to Dr Leronx, 21, Rue de l'École de Médecine, Paris.

An official medical guide to post graduate work in Hungary has been issued in English by the Hungarian Medical Post graduate Committee and the American Medical Association at Budapest. In addition to an account of post graduate work in Budapest and other universities in Hungary general information is given about the residences in the different towns. The book may be obtained from Dr Joseph Baló at the Central Office of the Hungarian Medical Post graduate Committee, VIII Maria utca 39, Budapest, Hungary.

A FRENCH commission, under the presidency of the Minister for Public Education, has been appointed to consider the methods of improving instruction in dentistry.

At the twelfth French Congress of Hygiene in Paris from October 20th to 22nd at the Pastour Institute the subjects to be discussed include the hearing of mental on social hygiene, Malta fever, and the decline of syphilis. A special number of the *Revue d'Hygiène* will be devoted to a report of the congress.

The issue of *Praxelles Medical* for June 21st is devoted to the life and work of the late Professor Depage.

The thirty first Congress of the Italian Society of Internal Medicine will be held in October, when the following subjects will be discussed: (1) Hepatic cirrhosis, introduced by Professors G. Sabatini and L. D. Amato, (2) Treatment of Graves's disease (conjoint meeting with Italian Society of Surgery), introduced by Professors A. Ferrata and P. Tiori, (3) Functional examination of the respiratory system, introduced by Professor G. Bocchi.

The third Spanish Congress of Pediatrics will be held at Saragossa in October under the presidency of Dr Borodío. Further information can be obtained from the general secretary, Dr Vidal Jordan, Sagasta 19, Saragossa.

The fourth Rumanian Congress of Otorhinolaryngology will be held at Bucarest, under the presidency of Professor A. Costina, on October 25th and 26th, when the following subjects will be discussed: Ozaena, by Professors Peimoff of Sofia and P. Rion of Cluj and Dr Tempoc, Rhinoplasty, by Dr I. Jirna, Treatment of cancer of the larynx, by Drs T. Nasta and L. Berner. Further information can be obtained from the general secretary, M. L. Meyersohn, 97, Callea Mosilor, Bucarest.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1 on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *JOURNAL* should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are: *MUSEUM* 9561 9562 9563, and 9564 (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR of the *British Medical Journal*, *Antiology Westcent*, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc.) *Articulate Westcent* London.

MEDICAL SECRETARY, *Medicines Westcent* London.

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus*, Dublin telephone 4737 Dublin) and of the Scottish Office 6 Drumshugh Gardens, Edinburgh (telegrams *Associate*, Edinburgh telephone 4361 Central).

QUERIES AND ANSWERS.

"W. H. N." asks for advice in the treatment of a patient who is suffering from persistent pythemia after extraction of the teeth for pyorrhea and caries. He had been suffering from general articular rheumatism; the flow is so copious that he cannot sleep.

HYPERIDROSIS

"M. B." asks for advice as to treatment of generalized hyperidrosis in a patient who has had localized tuberculosis of one lung which is now quiescent clinically and by x-rays, there is no pyrexia and no night sweats. The hyperidrosis occurs on slight exertion and on emotional stress such as interviewing people. The teeth are normal; he is not obese; his weight is normal for build and there are no signs of Graves's disease. Takes atropine sulphate gr. 1/400 i.d.s. but this obviously is merely palliative and seems to prolong the trouble. Would a ray treatment to the thyroid be indicated?

INCOME TAX

Retirement from Partnership

"H. A. B." retired from general practice on December 31st 1924, on which date he dissolved partnership, later he accepted a salaried post.

"H. A. B." is entitled to an adjustment in respect of his share of the partnership assessment on the basis that his share of the gross assessment for the year ended April 5th 1925 is three quarters of what it would have been if he had stayed in the practice until that date. Tax in respect of the remaining quarter—less any personal reliefs, etc., that may be due—will fall to the incoming partner to account for. Probably the best way of settling the matter is to explain the facts to the local inspector of taxes and ask him to furnish a statement setting out what adjustments will be due as between the partners and also with the revenue—if any. In 1925-26 he will not be liable to assessment in respect of his share of past book debts, but will, of course, be assessable on the salary earned in that year.

Appointment Abroad

"A. H." has been offered an appointment abroad, what will be the position if his wife and family reside in this country while he resides abroad and draws a salary in the currency of that country?

In our opinion he will not be liable—nor will his wife—in respect of remittances to this country made out of his earnings, either to his family or in payment of debts incurred by them for years in which he was not in the United Kingdom. But if in any financial year that condition fails for however a short time, he will then become liable to assessment as for that year in respect of sums remitted or brought to this country.

LETTERS NOTES ETC

"THE MEDICAL DIRECTORY"

MESSRS J. AND A. CHURCHILL (7, Great Marlborough Street, London, W.) write: The annual circular has been posted to each member of the medical profession. If the form has not been received a duplicate will be sent on request. We shall be grateful for the return of the forms by an early post.

THE PLURAL OF VIRUS AND PUS

In the last annual report of the Lister Institute *virus* was used as the plural of *virus*. We had supposed this to be a slip of the pen, or at worst an innovation. But a note by "C. T. O." in *Lancet* XIX of the Society for Pure English seems to imply that it had been used before. In the eighteenth century, he says, the plural of *virus* might well have been spelt *viruses*, which would have dissociated the word from such forms as *abuses* and *amuses*. We admit *buses* and must be content with *viruses*. The Latin *virus* is recorded only in the singular, so that a plural *virus* is inadmissible. If a pathologist is to write of different varieties of *pust*, he must for brevity have recourse to a plural *pusses*—for the true Latin plural *pura* would be unrecognizable, and *pusses* is already allocated. This raises obliquely the old and much vexed question about Latin words ending in *um*. When does such a word become so fully adopted into English that it takes the plural in *s*? Everyone not only writes but says *museums*, *gymnasiums*, *nastiums*, *harmoniums*, and probably most people nowadays say *sanatoriums*. We had supposed it time that *serum* followed recently, however, we received a note from the chiefs of a medical unit to the effect that the plural was still to be *vera* for the sake as we understood of euphony. Not everyone will agree but it is proverbially useless to argue about matters of taste.

BAKER'S ITCH

A CORRESPONDENT who is under the impression that the number of cases of baker's itch is increasing asks for further information. He is told that master bakers in his district will not employ a man or a woman unless the applicant signs a paper to the effect that he or she has never suffered from the complaint. A patient now under our correspondence care states that he knows of about seventy persons who are affected at present in the area. We have referred this matter to Dr. Haldin Davis who writes:

Considerable attention has been given to the subject of baker's itch during recent years especially since the war. Attempts have been made by the trade unions which safeguard the interests of the workers in the baking and confectionery trades to have this complaint added to the list of notifiable diseases so that their funds may be relieved from the burden imposed on them by members incapacitated by eczema. For this reason the

Ministry of Health instructed Dr A. Parsons to carry out a thorough investigation. His report (published in the *Journal of Industrial Hygiene* 1914 vol. 11 pp. 410-433) showed that on the one hand the impression in the trade of the widespread and increasing prevalence of the condition was erroneous; that many cases of baker's eczema or itch so called, were wrongly diagnosed; that the materials used in the trade were quite innocuous to individuals with normally healthy skins and that almost always the individuals who suffered from baker's eczema were those who worked in small bakeries where the mixing of the dough was done by hand and in consequence the skin was liable to maceration from long contact with the wet paste. Such conditions are of course well known to encourage the appearance of dermatitis. Dr. F. Rossier White of Wigau, a well known authority on industrial diseases of the skin, has also studied the subject and has come to the conclusion that the majority of the cases are incidents rather than consequences of the work. As regards some of the points raised in our correspondent's communication the various substances such as the glutins and the preservatives and bleaching reagents employed for the flour have all been tested and found harmless. The consensus of opinion seems to be that the best way to prevent the incidence of the complaint is to carry out as far as possible the mixing of the flour and water by machinery and to improve toilet facilities. At the same time we must also take leave to doubt the accuracy of the estimate put forward by our correspondent's patient of seventy cases known to him alone. Judging by the experience of the investigators of the Ministry of Health scientific examination of these patients would reduce their number to a very much smaller figure.

Jonah and the Whale

DR REGINALD COCK (Blackney Road, L.) in the course of some comments on the lecture on the psychology of animals swallowed alive delivered by Sir John Blund Sutton (JOURN. July 18th p. 104) writes: "With regard to Jonah Sir John states: 'In Matthew's Gospel the creature that swallowed Jonah is called a whale.' This is quite correct, but the word used in the Greek version of St. Matthew was *kytos* and is not restricted to its meaning to a whale or any cetacean, like the Latin *cetus* or *celus*; it may denote any sea monster—either a whale or a shark or a seal. The German word for a whale is *Wal* or *Walisch* and originally meant any large fish literally a roller (*Walzen* = to roll). Walrus comes from the same root and means a horse whale. Although two or three species of whale are found in the Mediterranean Sea yet it is unlikely that the 'great fish' that swallowed the prophet was a whale—as we understand the word to day. The only fish capable of making a really good job of it would be a large specimen of the white shark (*Carcharias vulgaris*), which sometimes attains the length of 30 feet. Gilus and Rondeletius record that a man in armour was found in the interior of a shark taken near Nice and that another shark when placed upon a car, was almost too heavy for a pair of horses to drag. Dr. Baird of the British Museum (*Cyclop. Nat. Sciences* p. 514) says that in the river Lugli below Calcutta he had seen a white shark swallow a bullock's head and horns entire.

LEPHER INJECTIONS FOR WHOOPING COUGH

DR C. B. THOMSON (Wimborne, Dorset) sends to supplement the correspondence which has recently taken place in our columns a chart showing the effect in diminishing the paroxysms in whooping cough of intramuscular injections of ether made deeply in the gluteal region. After the injection the number of paroxysms fell on the second day from fifteen to five and later to one and two. Three injections were given on three consecutive days, the first of 0.5 c.c. and the other two of 1 c.c.

TREATMENT OF INCIPENT DIABETES

DR T. FIFELDING WOODHEAD (Huddersfield) writes to confirm his statement (JOURNAL February 21st, 1925 p. 392) that red meats are concerned in diabetes insipidus. He reports the case of a married woman, aged 35, with two children, who complained of loss of energy and irritability, together with backache. The urine was colourless and the specific gravity 1035. All red meats were excluded from the diet and milk and white meats allowed together with rest and the administration of a bitter tonic. Within a week the specific gravity of the urine increased to 1012 and seven days later was 1020. Dr. Woodhead contends that the English people would be much healthier if they ate less roast beef, he maintains that all meat ought to be boiled.

RHEUMATIC AFFECTIONS

DR H. A. ELLIS (London) sends a note on two recent communications which he considers contained a portion of the probable truth about rheumatic affections and though appearing to differ were reconcilable. He observes that Dr. A. H. Douthwaite (JOURNAL June 27th, p. 1170) says that the principal precursors to rheumatism are lowering of the body resistance with radiating pain over the occiput following the course of the occipital nerves due to direct infection of the nerve roots or compression from inflammatory swelling, the alteration of the character of the skin in peripheral neuritis of the posterior nerve roots, muscular atrophy not due to disuse but to reflex trophic disturbance, and absence of hypochlorhydria. The treatment recommended was vaccine therapy. In the other communication, on arthritis deformans by Dr. L. S. Ashcroft and others (JOURNAL July 4th p. 13) it is stated (in addition to bacteriological findings) that the patients had hypochlorhydria and that treatment with hydrochloric acid relieved the condition. In the course of two dis-

cussions at the Royal Society of Medicine (JOURNAL January 24th, p. 162 and March 14th, p. 509) Dr. Ellis stated that in all forms of rheumatism a condition of neuritis existed which was probably granulomatous and might affect Hunter's nerve fibres, it certainly affected Hunter's non-somatic muscle fibres. He believed that the condition was originated by various causes, primarily of metabolic character and that it generally varied in incidence accordingly. Deficiency of acid was always evident in arthritis deformans as shown by the small amount or absence of urinary phosphoric acid and a great increase in the ammonium phosphoric ratio usually associated with a great output of magnesium. Another cause was an increase of phosphoric acid with defective elimination accompanying metabolic excess. Increase of the acid ratio in a single specimen of urine and diminution in the tide as characterized by hypercalcaemia of the shoulders and outer surfaces of the thighs and a decreased with an increase of relative output of uric acid. The prevalent or toxic causes were nearly always in the first or acid deficiency cases and benefit was almost invariably obtained by giving phosphoric acid. Dr. Ellis considers that this evidence supports his view that rheumatism is a condition of 'anionomic' neuritis activated by metabolic disturbance and associated with one of the three causes named which can be distinguished by urinary analysis and the patient accordingly treated effectively.

MESLES WHOOPING COUGH MESLES

DR HUGH SMITH (Dixons Green Duddies) writes: "In the middle of May this year a boy aged 13 years had measles. As soon as the measles cleared up he developed a whooping cough which he still (July 26th) has and during this last week he has again developed measles. There is no doubt about any of the infections. Is not this rather unusual?"

PRESERVATION OF BODIES FOR IDENTIFICATION

In the course of an lecture recently Dr. Waldo spoke of the advantages of the formalin preserving apparatus in use at the two courts over which he presides in the City and in Southwark. He said that it preserved the features and so was of use in identification that it did a way with any danger from infection was particularly useful in cases of death due to arsenic and other causes in which decomposition quickly sets in and in criminal cases where it may be necessary to keep a body for some time before burial. We understand that the cold chamber is generally considered to be better, and is in use in many Continental towns.

COW BYRES

DR T. M. ALLISO (Newcastle upon Tyne) writes: "An important point in preventing tuberculosis in milch cows is to do away with the central feeding passage in cow byres. If a cow comes into an clean herd and is infected with pulmonary tuberculosis it can be infected from and spread into the face and forehead of the opposite animal and thus spreads tuberculosis. All cow byres should be arranged with the cows' heads (in single or double lines) towards the wall where ample light and ventilation should be provided, and the wall should be lime-washed."

DOZING AT THE WHEEL

DR G. C. M. M. GONIGL (M.O.H. Stockton-on-Tees) writes: "On page 258 of the BRITISH MEDICAL JOURNAL of August 8th you print a leaderette under the title 'Dozing at the wheel.' It would appear unfortunately that unaccountable accidents of this nature are increasing in number. In all similar accidents it would be of value if coroners' juries inquired if an automatic windscreen wiper were fitted and if at the time of the accident this apparatus was in use. The automatic windscreen wiper swings backwards and forwards through an arc of a circle directly in the line of vision of the driver, and it is not unreasonable to suppose that this rhythmic movement might exert a hypnotic effect upon the driver."

CORRECTION

DR HELEN BOLLF calls attention to some little inaccuracies in this report of her evidence given before the Royal Commission on Lunacy on June 22nd and published in the JOURNAL of June 27th (p. 1188). The hospital referred to is the Lady Chichester Hospital, Hove, it has 39 beds (not 29). With regard to nursing homes she said the only bad nursing home she had ever lived in was to surmise in its dignity was one which was under supervision.

WIESBADEN WATERS

MESSRS HEPTZ AND Co. 9 Minning Lane, London E.C.3 have been appointed by the municipality of Wiesbaden sole agents in this country for the waters of the springs there for the salts obtained from them by evaporation and for other preparations.

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 31, 35, 38 and 39 of our advertisement columns and advertisements as to partnerships, assistantships and locum tenencies at pages 36 and 37. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 92.

British Medical Association

PROCEEDINGS OF SECTIONS AT THE ANNUAL
MEETING, BATH, 1925SECTIONS OF
SURGERY AND ORTHOPAEDICS.Sir BRUCELY MOYNihan, Bt, KCMG, MS,
in the ChairDISCUSSION ON
THE TREATMENT OF FRACTURES WITH SPECIAL
REFERENCE TO ITS ORGANIZATION
AND TEACHING

OPENING PAPERS

I—GEORGE E GASK, CMG, DSO, FRCS,
Surgeon and Director of the Surgical Unit, St Bartholomew's
Hospital

It is my duty to-day to open a discussion on the subject of the organization and teaching of the treatment of fractures. I have undertaken this task with grave misgivings because of the inadequacy of my powers to do justice to a most important debate, dealing as it does with a matter of education which may affect generations of students. My only comfort is a firm and strong conviction that the policy I uphold is the right one, and best calculated to bring about the result we all desire.

Statement of the Problem

The matter at issue is the best system to ensure that our medical students shall be well instructed in all the methods of treating fractures, so that when they go out into practice they shall be able to handle them in the best possible manner.

It may be admitted at the outset that at the present time something is lacking in our teaching and our way of treating fractures, and that a considerable amount of crippling results from want of knowledge and want of application of the best methods. It may also be admitted that the number of actions brought against practitioners in the civil courts may be taken as an indication of the accuracy of this statement—at any rate for the purposes of the discussion it may be taken as admitted. The matter has now been brought to a head by a vigorous article by Sir Robert Jones, published in the *British Medical Journal* of May 16th, 1925, and the action of this Surgical Section in choosing the subject for discussion.

Sir Robert Jones has delivered a slashing attack on the "Methods by which fractures are being dealt with at the big teaching hospitals"—an attack which may make some of us wince, and all think a good deal. As is right and proper, after criticizing destructively our present methods, with some of which I agree, Sir Robert goes on to make a number of very thoughtful constructive suggestions. The essence of these suggestions is a proposal that patients suffering from fractures should be segregated and placed under the charge of specialists.

I wish to make it perfectly clear at the outset that I do not enter into this discussion with any hostility to the aims and objects of Sir Robert Jones and his supporters for I am absolutely at one with them in these, I am entirely in agreement with them in holding that all is not well with the organization and teaching of the treatment of fractures, that reforms are necessary, and that for want of them patients may suffer from preventable crippling. I think that Sir Robert Jones has performed a bold and public-spirited service which deserves our grateful thanks. The only thing I challenge is the method by which he thinks the object he desires, and which we all equally desire, may best be obtained. I do not think that the way suggested—namely, the segregation of patients suffering from fractures and placing them under the care of specialists—will, in the long run, produce the desired result. I feel that there

may be great divergence of opinion on this point, and clarity of vision of our fundamental ideas on medical education is essential for the wise judgement of the problem.

Function of the Medical Schools

The hospitals were founded originally for the treatment of patients admitted to their wards, and the sole responsibility of the staffs of those hospitals was the treatment of the patients under their care. It is only comparatively lately that medical schools have become associated with some of these hospitals, and now the very grave responsibility of teaching generations of medical practitioners is added to the staffs of these hospitals. It is this grave responsibility that makes me ask you to consider the problem in its widest aspects, a problem which extends much further than the treatment of the individual patients in those hospitals.

Let us consider what is the function of medical schools. Is it to turn out general practitioners, well educated in the fundamentals of their profession, men who shall become capable of developing later into first-class general practitioners, specialists, or researchers, or is it their duty to turn out specialists? I think that the logical answer must be that the function of the medical schools is the sure grounding of the students in the elementary sciences, in methods of examination, and forms of treatment—in other words, the provision of an education in the best and widest sense of the word.

It is abundantly clear, however, that the education of a student on university lines would be lacking if during his period of training he did not have brought to his notice the ways in which advances in medicine are brought about. It is to my mind quite clear that advances in treatment cannot be sustained without continued improvements in teaching, and that improvements in teaching would cease to exist without the stimulus conveyed to the teachers by discoveries in science and the allied subjects, by research and pioneer work in all the branches of medicine and surgery. Far from decrying specialists, therefore, I hold that we need them, that we must have them, and that a university course would not be complete without them, but I do not think that they should have educative charge of the undergraduate student.

Divorcement of Surgery from Medicine

This discussion of specialism versus general medicine is no new thing, it is ages old. The first great division in the profession dates from 1163 and was brought about by Pope Alexander III at the Council of Tours, when an edict was enacted pronouncing that a practice which involved in its operations the shedding of blood was incompatible with the holy office of the clergy and forbade them to interfere with any matter of surgery.

That wise and far-seeing physician, Sir Clifford Allbutt, expressed himself on the matter in the following terms:

By the expulsion of surgery from the liberal arts Medicine herself was eviscerated the pernicious bisection of Medicine was made which has not yet spent its evil. The very foundation of the art was gone and the clergy and the faculties in France and England at any rate devoted all their energies to showing up the superstructure. Surgery had its revenge its bitter revenge but in the desecration of its own temple.¹

The effect of this edict was that the practitioners of medicine, who then almost all belonged to the clergy, "had to abjure manual occupation, and to content themselves with syllogisms and inspection of mines, often without any inspection of the patient himself" (Clifford Allbutt, *op cit*), while the operation of surgery was handed over to the uneducated and illiterate.

The effect of this edict of 1163 is still with us. It accounts for the present separation of surgery from inner medicine, for the bickering (now happily mostly good-natured) between physicians and surgeons, and it accounts for the artificial and most harmful distinction between the two subjects in our curriculum of education. It is my strong conviction that this artificial and totally unnecessary separation between surgery and medicine was the greatest blow the profession ever sustained, that it still constitutes a weakness to the profession, that any further splitting is to be deprecated, and that our best efforts should be towards union rather than towards further separation.

Growth of Specialism

During the past twenty years we have seen the growth of many specialisms, the formation of special societies for the study of special diseases and the institution of separate diplomas in special subjects. With these there can be no quarrel, because they are for the use and benefit of post-graduates—men who have had their original grounding and training in general medicine. It is necessary also for a man wishing to become an expert in one particular subject, whether it be golf or whether it be the use of a particular instrument, to devote a great deal of time and concentration of thought and effort to that subject. It is, of course, true that such a man who devotes himself to one subject, can excel in it and do better in it than those who spread their efforts over wider grounds.

Sir Robert Jones has instanced in his paper the great improvement which followed segregation of patients suffering from fractured femurs during the great war. This is perfectly true. The men who took charge of these patients became experts in their subject and as the result of their work notable reductions were effected in the mortality and disability resulting from this class of wound. Similar sorts of results were obtained in munition factories, where men and women spent their time making one little part of a machine and thus became incredibly expert at it. I cannot believe, however, that this is a good argument to apply to the education of medical students.

Reason for Specialism

The cause for this growth of specialism which has been so marked a feature of the past twenty or thirty years may be ascribed to the enormous impetus given to medicine by the discoveries of Pasteur, to the resulting facilities given to surgery, and the rapid improvements in instruments, technique and manipulative methods. It has been found impossible for ordinary mortals to keep pace with these rapid improvements, and impossible to obtain expert skill in all branches of the profession and with all sorts of instruments. In consequence specialists, men desiring to acquire expert skill in one or more subjects, have arisen. The advances made by these men have then spread slowly but surely, throughout the whole profession, so that the standard of medical efficiency has been raised to a higher point than it has ever been before in this country. This fact important as it is constitutes no argument, however, that students should be taught along the lines of specialism. The principles of treatment are the same in all types of injuries and diseases, and what is needed is a firm grounding in the fundamentals.

The Medical Curriculum

These improvements in medicine and surgery have been reflected in the medical schools. The medical curriculum has been altered from time to time to meet the ever-changing needs. It has been demanded that students should receive instruction in, and show themselves competent to recognize and treat, diseases of the eye, nose, and throat, and to take special courses in lunacy, fevers, anaesthetics, and many other subjects. This curriculum has become overloaded, and there is danger that it may become even more so, and in our desire to teach students something of everything the main great principles of education may be forgotten.

Quite recently, for reasons that appeared to be sufficient, patients suffering from venereal diseases and tuberculosis have been segregated for the purpose of special treatment, and students no longer meet with these diseases in the course of their general training. I have no hesitation in saying that, from the point of view of teaching the undergraduate student, this has been a disadvantage and not an improvement.

As an illustration of the way in which the objects of the specialists may be relieved, while preserving at the same time the best system of education, let us consider the subject of urology.

The improvements in this branch of surgery, which have been very rapid, date from the introduction of the cystoscope, the use of which has made possible the diagnosis of many affections of the bladder and kidneys which previously

were obscure. Following the introduction of the cystoscope there came in rapid succession the invention of special methods for the accurate estimation of the renal functions and many other improvements. A new specialty arose. In some hospitals special urological clinics were formed, and in the Royal Society of Medicine the men interested in this subject split off from the Section of Surgery and formed themselves into a special subsection for urology. In my opinion this action has not resulted in benefit to them either as to surgery as a whole.

I have a very clear recollection of the discussions that took place in my school as to the wisdom or advisability of establishing a department of urology, with special wards under the care of a specialist. After many long debates it was decided that this should not be done, but since of the younger surgeons who had leanings that way made themselves proficient in that art, and very soon they began to teach the other surgeons, and, what is more important, the younger men, the house surgeons and assistants. The result is that at the present time all the younger men are beginning to use the cystoscope in their ordinary work, even as a physician uses his stethoscope, and the standard of urological work, though it may not be as high as in the best urological clinics, is still, I am proud to say, quite good, and we are not ashamed of it. What is still more important, the student sees these cases while he is doing his ordinary surgical work, and he begins his professional life, not feeling that there is any mystery about the cystoscope but knowing that it is an instrument that he can master and use himself with a little practice.

It seems to me that here we see the right and natural development of a specialty and its gradual diffusion into the realm of general medicine. I confidently anticipate that before long we shall find the cystoscope in as common use in the medical wards and among medical practitioners as the stethoscope and the ophthalmoscope.

It has been suggested, and even asserted, that at the present time the teaching in the surgical wards of the big hospitals with teaching schools no longer gives the student a general education, and that, in point of fact, the general surgeons have become one-sided specialists caring only for diseases of the abdomen—to such an extent that the teaching on other subjects, including fractures, is in a great measure neglected. No doubt there has been a tendency in this direction, and the spectacular surgery of the abdomen has obsessed some surgeons and caused them to pay too little attention to other complaints. But to say, as has been said, in a leading article in the *BRITISH MEDICAL JOURNAL* of May 16th, that most surgeons in general hospitals must be classed as abdominal surgeons, is in my opinion a grievous error and most misleading.

The Remedy

It may be admitted, however, that there is some ground for complaint, and that, of late years, the teaching of fractures has not received as much attention as the subject merits, and that from the national point of view more good might be done by preventing the deformity and crippling following fractures than by doing heroic operations on patients suffering from inoperable forms of cancer.

What is the remedy for this state of things? Sir Robert Jones has made some very definite and drastic recommendations. I think he has gone too far, and if the reforms he suggests were carried out we should have a medical curriculum loaded in watertight compartments and even more confused than it is at present. What would be the outcome if it were admitted that patients suffering from injuries or diseases which were not being treated successfully should be segregated? Surely the logical answer would be that next year someone would say, "The results of operations of an epithelioma of the tongue or mouth are atrocious. Let a special stomatological department be formed, placed under the care of specialists, and let all the students be passed through this department, that they may go into practice equipped to fight this disease." Another would want a department for the stomach, and another for arteries, and so *ad infinitum*. On these lines medical education would become impossible.

All the same it is right and proper that each university should possess centres of specialism where men can devote

themselves after qualification to special studies, but in medical schools we should endeavour to strike a proper balance, and by wise judgement spare out the time allotted to clinical studies in the best possible way.

How, then, can the teaching of the treatment of fractures be improved in our medical schools? The very fact that a challenge to them has been thrown down and that this discussion has taken place will have an effect. Medical schools are very sensitive to public opinion, and the school committees are ever watching advances in medicine and striving to keep all departments under their eye up to date.

It is of great importance also that some of the surgeons should make the subject of fractures their interest in the same way as has been done in urology. It has been done before and may be done again, we need not be reminded of the names of Lane, Liston, and Bryant. At the same time I think that something more is wanted, and I would welcome the foundation of a special hospital in London for the treatment of fractures under the care of specialists, a hospital in which the best methods could be shown and from which light would spread.

Another reform which might well be achieved is the way in which patients suffering from fractures—generally of the upper limb—are treated in our casualty departments. Patients with minor fractures, and fractures of the humerus and radius and ulna, are not usually admitted as in-patients, too frequently they remain under the care of junior and inexperienced house officers. These patients are not as a rule admitted to wards of the hospital, because the beds are too few, and there are long lists of patients suffering from serious complaints whom humanity compels to take in, while a man with a fractured forearm can be treated as an out-patient. It is probable that, from the point of view of the State, it would be a far better business proposition to render a wage earner with a fractured forearm fit to return to his work, rather than to perform a colostomy for a patient suffering from intestinal obstruction due to an inoperable carcinoma of the rectum. Yet humanity demands that a patient suffering from intestinal obstruction must be admitted and operated on, while the man with a fractured forearm must only too often give way, because the available beds are too few to accommodate both.

As regards London I feel sure that at the bottom of the trouble lies the acknowledged shortage of beds. An attempt to remedy this shortage has been suggested by taking over the hospitals now administered by the Poor Law, and it is to be hoped the remedy may not be long delayed. In order to meet this shortage some hospitals are trying to remedy the defect by making out-patient ambulatory fracture clinics, to which all patients who can walk are sent, and these patients are placed under the care of one man, who may or may not happen to be a surgeon, or an orthopaedic surgeon, or an electrotherapist. Others, on the other hand, are enlarging and increasing the scope of the massage and physio-therapy departments. It is evident, therefore, that all the hospitals are not blind to their shortcomings, and each "must contrive the times to their necessities."

The conclusion of my argument is that it would not be in the best interests of medical education, and therefore in the long run to the public advantage, that patients suffering from fractures should be segregated and placed under the care of specialists. Though certain reforms in methods of teaching and organization are needed, there is evidence that attention is being paid to them, and that as opportunity yields, and more beds are provided, the necessary changes will become possible.

I earnestly hope that it will not be thought that I have entered this discussion with the idea of upholding the status of a general surgeon against that of the specialist, or in any spirit of hostility to specialism. My aim has been to argue the point which has been raised on medical education, in which I am deeply interested, and have a certain responsibility. For these reasons I welcome this discussion, and have no doubt that a free debate will tend to clarify our views and be of advantage to us all.

REFERENCE

¹ Clifford Allbutt. *The Historical Relations of Medicine and Surgery*

II—Sir ROBERT JONES, K B E, C B, M CH, F R C S

In an address delivered in May¹ I dealt in detail with the problem of teaching due to fractures, and ascribed it to the fact that the organization and teaching of fractures left much to be desired. The neglect of this important branch of work is mainly due to the rapid advances made in abdominal surgery, which fascinates the young surgeon and offers him a comparatively rapid path to fame and to fortune. A gastro-enterostomy or appendectomy is soon over, and, while it demands sound judgement and careful technique, the surgeon's care and responsibility ends with the healing of the wound. The setting of a fracture also requires considerable knowledge and technical skill, but this has to be continued without relaxation for many weeks, and often for months. With the advent of x-rays, and consequently a critical public opinion, the surgeon's responsibility and anxiety are considerably increased. A fracture, therefore, is not regarded as a kindly gift by the average surgeon, and is often handled under considerable stress and strain. The fracture may be simple or complex, easily dealt with or presenting great difficulties, but to the patient this makes no difference, he expects functional perfection, and unless this is obtained the surgeon is in trouble, whether he deserves it or whether he does not.

All this would lead one to expect that special effort would be made to perfect our diagnosis of fractures, revise and simplify our treatment, and render our teaching beyond reproach. Unfortunately this has not happened. On the contrary, our handling of fractures shows but little improvement, and our students are inefficiently equipped. Before abdominal surgery became a specialty and radiography the rule the older surgeons spent a considerable time in teaching the student the principles of diagnosis. In these later days the diagnosis is usually made in the radiological department, and students have but little opportunity of observing the methods of investigation of which many of the older surgeons were masters. If the case is one of fracture of the elbow it is usually sent directly to the x-ray department, and the student is often deprived of the opportunity of discussing the differential diagnosis in such interesting conditions as separation of the epiphysis, supracondylar fractures, separation of the epicondyle, fractures into the joint, fractures of the neck and head of the radius, or separation of the coronoid, any of which can usually be discovered with but little disturbance to the patient. I quite admit that no opportunity should be lost to procure an x-ray picture. It is an essential adjunct to accurate diagnosis. Twenty-five years ago I wrote:

The advent of the x-ray has added immensely to the accuracy of our knowledge and to the classification of our cases, and has saved our patients from much unnecessary and often aimless manipulation. We must however beware that we do not paralyse our diagnostic faculties from pure mania. The Roentgen ray should not usurp every other diagnostic means at our disposal.

A revival of interest in the management of fractures followed the intervention of Arbuthnot Lane, for whose pioneer work I have the greatest admiration. Moved doubtless by his observation of deformity due to malunion, he advocated the plating of most of the fractures of long bones. I do not wish to enter into the controversy to which this method of treatment invariably gives rise, but I would like to point out the fact that here was a field which appealed to the operating surgeon the world over, and hospital beds were readily found for all. Operation was looked upon as the last word, and success or failure depended upon the skill or otherwise of the operator. In the hands of a comparatively few the results were good, and little harm was done even in those cases where mechanical means would have alone sufficed. As a routine operation in the hands of the less capable and discerning, however, tragedies were plentiful, and we can all remember cases where the femurs of small children were plated, and where plates or screws were used to solve the problem of a Colles's fracture. Now that a reaction has set in I question whether beds can be as readily available for simpler, safer, and less dramatic methods.

We are met to discuss the organization and teaching of fractures, and this necessarily involves the question as to

whether we are satisfied with the treatment of fractures as we meet them today. If we are satisfied there is no need to change our organization or our teaching. If we are dissatisfied with what we see of results, then it is surely necessary that radical changes should be proposed. I question whether any surgeon who has given serious thought to the problem can remain complacent and satisfied with conditions as they exist. Indeed, from my inquiries and experiences a strong feeling exists to the contrary, shared both by the practitioner and by those whose responsibility it is to teach.

If any proof were needed of defects in organization and teaching the great war supplied it. All honour to the medical officers who worked so hard and so conscientiously. They cannot be blamed because the difficulties thrust upon them were often such that it was not humanly possible to overcome them. Men with no experience in the management of fractures did the best they could, while others with experience were confronted with appalling conditions. Splints of every variety, ancient and modern, were thrust upon them, immediate evacuation was inevitable, and continuity of treatment impossible. No wonder that in the early stages of the war excessive shortening and malunion were, I could almost say, the rule. By organization and intensive instruction under very adverse conditions a very satisfactory change was effected during the later stages of the war. This was notably the case in fractures of the femur. During 1916 the mortality from compound fractures of the femur amounted to 80 per cent, by 1918 it was reduced to about 20 per cent. This was due to organization and teaching. The men were thoroughly taught the use of one splint—in this case the Thomas's knee splint. The organization consisted of team drill, application near the firing line, segregation, and continuity of treatment. To Henry Gray and Maurice Sinclair much of this reform was due. Few know as I do the difficulties under which Sinclair laboured, and the skill and care with which he treated his wounded team work and segregation at Boulogne solved the tragic problem, and ended—is far as that district was concerned—errors of alignment and undue shortening. When his cases arrived in England, however, organization was far less perfect. There was no attempt at segregation, cases were distributed in obedience to the conveniences of transport, and then treatment was by no means efficient. Splints were removed too soon, changed unnecessarily, and often no protection applied during walking. It was only when permission was granted to segregate fractures in this country and terms were brought over from abroad to secure continuity that the chapter of disaster was finally closed. What was the result? Under the supervision of men like Pearson at Edmonton better results were obtained than could be shown in any of the hospitals before the war. The average shortening was half an inch in a group of many hundreds, several of which were of the worst type of compound fractures, not one of which was plied. If such treatment were organized at home there would be no need for this discussion to day. The difference between these results and those in previous times may be emphasized by the statement of a surgeon to a large teaching hospital, who said of the femur, "I am satisfied if the shortening is not more than from one to two inches." Let it be understood that the improvement in the treatment of fractures during the later stages of the war was due to expert supervision, simplicity of apparatus, team work, segregation, and appropriate after-care. These are the lessons of the war. Are we going to apply them, and improve upon them, or leave things as they are?

If reform is to come about it is essential that the large teaching hospitals should give the lead. Their responsibilities are grave and far-reaching, for we depend on them to sow the seed of precept and example to generations of practitioners. Furthermore, they have the means at their command, both as regards personnel and equipment. They do, I venture to think, need a more modern vision of the needs and difficulties of the practitioner. I am pleased to find that in Leeds reform and segregation have already taken place. This is what we might expect in a school dominated by our distinguished President and

governed by unique traditions. It is true that other hospitals are making efforts, but none of them have so far reached the promised land.

The teaching of the treatment of fractures can only be productive when based on the principles which govern the prevention and correction of deformity. Skill in the application of splints, though important, is secondary. The problems must be thought out in relation to function. Every fracture is a potential deformity, and the deformities, when they come, often do so insidiously. They may arise while treatment is being carried out or when treatment is completed. Splints may be so applied as to admit of a sagging of the femur, or taken off too early for the bone to resist the incidence of body weight. The external contour of a forearm may appear normal when it hides a cross union. The surgeon before he undertakes to teach should have the knowledge which will enable him to visualize all possible calamities, and impart this to his student. What actually does occur? In most hospitals ambulatory fractures are treated by junior officers with little or no supervision. These officers often have no special experience or knowledge, and the decision as to whether a case is admitted to the ward or not lies in their hands. Their office is a very transient one, because the post is subsidiary and merely a stepping stone. The junior officer does not even remain long enough in his position to acquire a practical knowledge. It is difficult for him to know enough to give sound instruction. He learns largely by his mistakes, which are usually repeated by his successor. This constant change can bring no credit to the hospital, nor will it admit of useful guidance to the student. We are not much better off when we deal with the recumbent case, for it is generally left in the hands of the house-surgeon. The honorary surgeon may at times see the patient, but often he is but little interested in this type of case, and rather resents the occupation of a bed which may exclude a more acute admission. The pernicious doctrine of early evacuation is therefore practised. The leg is put up in plaster, and the case sent out on the earliest occasion. This is a deplorable routine, productive of endless trouble, and can only be safely practised very occasionally. But once the patient is out of the hospital the surgeon rarely sees him again—a few visits to the out-patient department, and then the usual round of hospitals.

As I have often said, there is a fault about the plaster case which does not admit of compromise for it assumes the reduction to be immediate, complete and ended. A readjustment of the bone ends cannot take place. The reduction of a difficult fracture is not the work of a moment, but often of days. Many fractures of the shaft of the femur are treated in this way, and as for fractures of the neck of the femur, they are usually sent to the Poor Law infirmary without the aid of the student's vision, let alone education. Surely this is not an ideal state of things. I do not think it could occur if the surgeon were interested in fractures, and once it is admitted that he lacks an interest we may safely infer he lacks in efficiency and in that knowledge and enthusiasm so necessary for a teacher to possess. To the patient, and to his family, it is of paramount importance that he should leave hospital with the certainty of restored function, and that convalescence should be as short as modern methods can ensure. To a surgeon who takes pride in his work the full recovery from a bad fracture should be a source of gratification, while malunion, stiffened joints, and industrial disability should correspondingly fill him with remorse. The effect on the medical student is deplorable if he is brought up in an atmosphere where the teaching of the treatment of fractures is placed on a subsidiary plane. When he is qualified he pays a bitter penalty. It is the one department of medicine in which mistakes cannot be hidden, and which the public never forgives. In a country district the hunting hump is a perpetual menace.

I have only time briefly to indicate the type of mistakes which are in constant evidence in our hospitals and consulting rooms. Many of them are due to errors in alignment. I cannot too often repeat that an end to end

opposition in a femur with imperfect deflection of body weight is infinitely more serious than overlapping with correct alignment. The smooth working of a limb depends on preserving the true axis of movement of a joint, so that the stresses of action may act across the joint on normal lines—otherwise abnormal stress will produce abnormal strain. Many crippling deformities are due to want of recognition of this point. Again, let us instance fracture of the neck of the femur, the treatment of which is sometimes never seen by the student. We know how difficult such a case becomes when initial treatment has been neglected, and the shortened leg with internal rotation and lack of abduction presents itself. Such a case, seen and treated early, could have been saved from shortening and adduction even if bony union were not secured. How common it is to meet the angular lateral deflection in fracture of the upper tibia, and how easy to prevent it. In the tibia how commonly we see a knock-knee due to the error of obliterating the outward curve of the tibia, and in Pott's fracture—one of the simplest problems—how often the deformity persists because the practitioner has not been taught how to reduce it. Perhaps the elbow foras one of the commonest objects of disability and deformity, and yet with care in the reduction and the abolition of the internal angular splint it should prove a very satisfactory joint to treat. These defects and deformities could be many times multiplied, but they will serve to recall experiences constantly recurring.

A frequent source of error is to be traced to deficient instruction in prognosis. The student can rarely tell us the length of time which it takes for a broken limb to bear the brunt of body weight. A patient may leave a surgeon with a limb of normal form and length, and in a few weeks it will become short and crooked. He should know that a bone which cannot be moved by a manual examination often yields to a superimposed body weight, and therefore protection against telescoping and lateral deviation should form part of after-care. In spite of a well equipped physiotherapy department attached to the hospital, how few students are able to instruct a masseuse or direct a gymnast, or show an electro-therapeutist the muscles he should stimulate. I fear sometimes the surgeon himself has not the necessary knowledge to instruct. How few students have been taught to differentiate between the joint that requires rest and that which requires movement, or to handle a fracture with a minimum of pain, how to feel for crepitation, how to avoid muscular spasm, and to reduce a fracture almost painlessly by securing muscular relaxation. The rough handling of a fracture by the careless or unskilful is indeed an unpleasant sight. There is something radically wrong with a syllabus which leaves a student ignorant in matters of such vital importance to his future.

Now it is easy to be iconoclastic, but very difficult to be constructive. Before reconstruction can occur it is necessary to admit the necessity for it. I venture to hope that we are all convinced that things are not as they should be, for the evidence around us is overwhelming.

First let me deal as lightly and briefly as I can with our teachers. I would lay it down as an axiom that no man should bear the responsibility of teaching the treatment of fractures unless he is really interested in his subject. It is too heavy a charge upon his conscience. Whether he calls himself a general surgeon or an orthopaedic surgeon is of little importance compared with that of knowing his job. It is futile to bandy the term "specialism" or to speak of an encroachment upon the domain of the general surgeon. We are all specialists in practice when we devote our heart and mind to any particular group or type of case. It must be abundantly obvious that the day is passed when any one surgeon can adequately cover the constantly extending domain of surgery. The war proved this beyond question. Team work and segregation in many fields of surgical endeavour saved the lives of many thousands, and incidentally the reputation of surgery. Whether we submit gracefully to it or not, every surgeon in the future will be judged by the work he does in some special group of cases. Even now consultations are offered us, not because we are general surgeons, but because we excel in this or that. It is a relic of early days that in a general hospital we are

expected to do everything, whether we do it well or badly. A sound education in general surgery is a primary necessity, whatever the branch we favour later. Some of us choose the abdomen, others the extremities. Whatever we call ourselves our line of conduct is the same—we strive to excel in work congenial to us, and we succeed because of that fact. The orthopaedic surgeon is naturally interested in fractures because his mind is attracted to mechanical problems and to the prevention and correction of deformities. Let the general surgeon to whom fractures appeal continue to teach and treat them, for he at least possesses the qualification which I postulate as essential—namely, interest in the work. Such a surgeon will not be content to leave his cases in the hands of his house surgeon or feel happy when they are bundled out of his wards in plaster cases.

The treatment of fractures, therefore, must be placed on a different plane, and our students must be taught by teachers who are wisely chosen. After consultations with my friends Rowley Bristow and Harry Platt, who may be considered representative of the metropolitan and provincial schools, I would suggest the following scheme, based on certain general principles.

- 1 The necessity for the segregation of in-patient fractures either into (a) wards under the control of a special surgical unit, or (b) in special wards not allocated to one unit alone.

- 2 The creation of a special out-patient fracture clinic, to be included with the fracture wards as part of a general scheme. Out-patient fractures should not be dealt with as a separate entity—in other words, their control should be under the surgeon or surgeons in charge of the fracture wards.

- 3 A surgeon in charge of the fracture department should be a consultant, the director of a unit, and one in whose practice and teaching the treatment of fractures will be maintained during the whole of his active surgical career. If there exists an orthopaedic department, as should be the case in every teaching hospital, the chief of this department should be one of the surgeons in charge of fractures—even if he is not the only one.

In an ideal scheme the fracture wards should form part of the orthopaedic service, this would simplify both the organization and the teaching. It is certain that no real advance in the treatment of fractures will ever take place if the department is placed on a secondary plane, which is inevitable if the system is inaugurated or maintained of leaving it under the control of a junior surgical officer, who makes this position a mere stepping-stone to some other surgical post.

The fracture team should consist of

- 1 One or more surgeons, including the orthopaedic surgeon.

- 2 A senior assistant. This appointment should be well thought out, and only given to a man with special qualification for the post. There should be security of tenure for a period sufficiently long to make him not only expert, but to secure his skill for the training of the students. He should display special interest in the surgery of the extremities, and preferably intend to follow it up. I consider that the success or failure of the department will largely depend upon this appointment. It may be asked, "What is to become of this assistant in after-life? How is he to earn his living?" Is there room for fracture specialists in private practice?" My answer is that if the right man is chosen for this post he will almost surely gravitate to orthopaedic work, where his knowledge will be of the greatest service, and form an integral part of his expert education.

- 3 The third member of the team should be a physiotherapist, preferably the chief of his department. In addition to these there will be the house surgeons, who attend the clinic as part of their duties, dressers, and clinical assistants.

- 4 Another most important member of the fracture team should be a sister, specially trained, who should be in charge of the fracture ward. She should remain

in undisturbed possession. The care and nursing of fracture cases requires very considerable skill and training, and it is essential that the sister should not be transferred to other departments.

If the fracture ward is under the control of more than one surgeon the first assistant should be in the service of all. He will maintain a salutary rivalry between his various chiefs, which is an important step towards efficiency. I lay the greatest stress upon the segregation of fractures in special wards, even in those hospitals which do not specialize in teaching. It avoids for healthy criticism, and often leads to much needed introspection. Surgeon A, with a case of shortened malunited femur, will realize his limitations when he sees what Surgeon B can do with a similar injury. Surgeon C may feel that his reputation would be enhanced if he handed over his fractures to a more interested colleague.

In the first place, once or twice a week there should be an out-patient fracture clinic, which all senior students are obliged to attend. At least twelve attendances should be compulsory. No formal lectures are needed, but instead a series of clinical demonstrations, in which groups of fractures are collected and compared, and instruction given in relation to diagnosis, prognosis, and end results. More especially the student should be taught the principles that underlie the prevention of deformity and its correction. The tuition must be direct and simple, most of the time being devoted to the common fractures with which the practitioner is likely to meet. The x-ray department, with the wealth of information it represents, should be in close touch with the fracture clinic.

At this stage I should like again to emphasize the urgent necessity there is for each hospital to secure its useless splints and return for teaching purposes only those of known efficiency. Hospital staffs should, from time to time, meet and select the most useful—and they are generally the simplest—splints, and no student should graduate unless he has completely mastered their correct application. Furthermore, in order to simplify the training and to stabilize the examination of the students this idea could be extended by the formation of a committee, representative of all teaching hospitals, to decide upon the best type of splints.

This would be of immense service in a national emergency, and would save the student much waste of time. It is a haunting thought that many thousands of lives would have been saved abroad if every surgeon had been taught to apply splints correctly and expeditiously, and if only those splints had been at hand whose efficiency had been tested. We were able to be of considerable help in this matter to our American colleagues, who learnt from our mistakes, and they published an illustrated little handbook of splints, simple in construction and effective in use, which every surgeon had to master thoroughly. Instruction in a fracture clinic such as I have outlined would have met the urgent need in the great war, and such dire experiences as we encountered in its early stages should leave an indelible impression upon our mind and conduct.

The instruction carried out in the out-patient department should next be continued in the fracture ward, where the best methods of dealing with the recumbent cases could be taught.

I venture to suggest that the scheme I have formulated is neither difficult in conception nor revolutionary to bring into effect. There is sometimes a natural inclination on the part of the general surgeon to resist what he fears to be an encroachment of specialism. This, I am happy to think, is less evident than in days gone by. There is no more circumscribed a specialty than that of the surgery of the abdomen. Many men who have excelled in other departments of surgery have told me they would be glad to hand over their fracture cases, but, they ask, "To whom?" Without a fracture department there is no remedy for them. There can be little doubt that many surgeons would, to their advantage, prefer to leave such cases in the hands of a fracture team rather than be held responsible for mistakes, which are bound to be made by inexperienced juniors. Even if they did not hand their

cases over to a colleague, they would welcome the assistance of an expert first assistant.

Another criticism likely to be levelled against this scheme is that the student's curriculum is already too overcrowded. This does not bear examination. We do not wish to crowd the student's mind, on the contrary, we desire to simplify and clarify his instruction. By securing expert men to teach we exclude much waste of energy. His education becomes intensive instead of being diffuse and desultory. He is taught what is necessary and practical by teachers who have a real knowledge and interest in their subject. When we find students crowding the operating theatre on every opportunity, watching work they will probably never be called upon to do, and this for years, we appreciate how valuable time is wasted. It is doubtless necessary that they should know something of intricate and rare cases, but the out-patient department affords them a better equipment in after-life than academic lectures, the matter of which they can equally well glean from textbooks.

Another objection that may be urged is that our hospitals are already too crowded, and that the so-called chronic cases should not be allowed to exclude the acute ones. This is but poor comfort to a young working man sent off to a Poor Law infirmary with a wife and family dependent upon him. It is inefficient treatment and neglect which transform a simple fracture to a chronic deformity. It is far better for our hospital authorities to say "We are not prepared to treat fractures," than that they should take on responsibilities which they cannot meet. The responsibility is not met by sending a fracture of the femur from their door directly to a Poor Law infirmary, unless they know that its staff and equipment can meet the demand. We cannot disguise the fact that great numbers of adult cripples are manufactured by want of adequate provision. If our city hospitals admit that they cannot cope with the problem for want of beds, wards should be procured in Poor Law infirmaries or other institutions. These wards, however, should be fully staffed and equipped, and brought into close association with our teaching centres. But whatever the arrangement, the student should have the full benefit of it. There can be no justification for any system which adds to the complexity, and not to the relief, of our cripple problem.

GENERAL DISCUSSION

Mr S W DAW (Leeds) said he was asked to speak as a general surgeon in view of his long connexion with general surgery before confining himself to orthopaedic work. But in either case it was necessary to approach the subject in a spirit of detachment. They were chiefly concerned at that meeting with the interests of the medical student so far as they were compatible with the best interests of the patients, for there seemed to be no difference of opinion as to the great need of improvement in their methods. On the one hand, it was proposed that surgeons should take more interest in fractures and that more beds should be provided. The hope was expressed that these beds would be provided in Poor Law infirmaries. This was segregation indeed, and would seem to defeat the aims of those who wished to keep fractures closely associated with other branches of surgery. On the other hand, it was proposed to segregate fractures in special wards either under the care of an orthopaedic surgeon, or otherwise under the care of general surgeons as before, but with the special services of a resident fracture expert to act under the general surgeons. The chief difficulty appeared to lie in finding and retaining the services of the resident fracture expert. To make such a post attractive he thought it would be necessary to associate his duties with orthopaedic surgery generally so that the fracture surgical resident should act also as resident to the orthopaedic surgeon, in addition to his work on fractures under the general surgeons. He believed that the appointment of a resident fracture officer would go far to meet the requirements of the patient, whether that officer worked

under the general surgeon or under the orthopaedic surgeon. As to the welfare of the student, that depended mainly on the efficient treatment of the patients. Each student should be obliged to put in a definite number of attendances in the fracture wards where he would follow and assist in the practical application of splints by the resident fracture officer, and would also receive instruction from the surgeon in charge. In that way the student would see the application of approved methods and be kept in touch with any advances in treatment.

Dr ROBERT B. OSCOON (Boston, U.S.A.) said that the position which Sir Robert Jones had taken seemed to be unsatisfactory, and of pre-eminent strategic importance in the advance of surgery to which they all looked forward with hope and conviction. As Mr Gask had said, on this they were agreed, it was only a question of method of attack. Insurance companies and workmen's compensation boards in America were concerned with the treatment which accident and industrial fracture cases were receiving at the hands of the medical profession. It would probably be fair to say that in only a small proportion was wage earning function restored in the number of weeks which it seemed reasonable to expect from the textbooks and from the progress of the rarely well treated case. An extreme example might be cited in a fairly common but frequently unrecognized compression fracture of the spine. Sever had found that the average time of over twenty months had elapsed before such a case was reviewed by an impartial expert and the correct diagnosis made. The waste of time to the individual, the industrial company, and the State was appalling. They were finding the profession wanting, and the insurance companies were actually establishing clinics themselves. This, it must be admitted, was rather a reproach to their treatment and teaching. They were trying to meet it in two ways: first, by stimulating the interest of the general practitioner in these common injuries by affording him an opportunity to observe and learn well tried and practical methods of treatment; secondly, by crystallizing the opinion of the most expert and experienced surgical minds. This was not an attempt to standardize narrowly the treatment of every fracture, but an endeavour to reach an agreement as to certain essential conditions which must be satisfactory, and, if possible, to suggest simple and efficient methods of handling the common types. It was not as if the best methods of treatment were still very debatable, at least in America. The unfortunate mass of material in the war had largely settled these questions. That such attempts might be fairly successful was evidenced by an illustrative outline of the treatment of fractures, which was approved by a group of surgeons of wide experience and active practice in the treatment of fractures after a two days' conference under the auspices of the fracture service of the Massachusetts General Hospital. They came from widely separated cities. This outline, which the speaker presented, was published in the *Archives of Surgery*, and had had a very wide distribution. Such documents possessed a certain authority, and when published must influence medico-legal opinion. It soon became necessary for the practitioner who essayed to treat fractures at least to know and practise these or similar methods if his work was to stand the test of his patients' approval and favourably influence the opinion of the jury. To some extent they had complied with Sir Robert's requirements. Dr Charles L. Scudder, visiting surgeon to the Massachusetts General Hospital, which was one of the most conservative of American hospitals, succeeded many years ago in establishing a fracture service in the wards and out-patient department of that hospital. This service had grown both in number of cases and in its scope of treatment. It was now a rotating service shared by the general, surgical, and the orthopaedic services. Weekly visits to the outdoor fracture clinic were followed by visits to the ward cases by all the members of the staff, and a free discussion of methods and end-results ensued. This had proved instructive and stimulating to students and practitioners, who largely attended this visit. This service made possible the conference which had been mentioned. Friendly rivalry in methods and results was one of its best features. A National Committee on Fractures, of which Dr Scudder

was chairman, under the auspices of the American College of Surgeons, held several meetings a year, and its individual members organized in their own communities clinics to which local surgeons treating fractures were invited. The response had been most encouraging. Already this National Committee had approved a list of emergency splints and apparatus which, with the influence of the American College of Surgeons, would undoubtedly be accepted as a minimum standard by every first-class hospital. Railroad companies were now applying for descriptive lists of this equipment.

They agreed with Mr Gask that the teaching of the undergraduate should be as little as possible along the lines of specialism, but surely the teaching of the treatment of fractures should not be considered as specialism, and the need for teaching was intense. A review of the teaching of fractures in the best medical schools of America made it evident that much was yet to be desired. One of the best plans of teaching was that now in operation at the Johns Hopkins School, under the direction of W. S. Brier, professor of orthopaedic surgery. Fractures were assigned in rotation to the different surgical services and to the orthopaedic service, and the responsibility for their treatment was delegated to members of the staff especially interested in fractures. Four students at a time were on telephone call for stated periods, were notified as soon as a fracture case entered, and were obliged to follow the case throughout the entire period of emergency and convalescent treatment. At stated periods also a general fracture clinic was held, this was attended by the students, the surgical and the orthopaedic staffs treated the fractures, and the end results were studied. There were in addition clinical lectures on fractures, and instruction in the application of different types of apparatus. At the Harvard Medical School instruction in fractures began with a course in surgical technique in the second half of the second year. The students who had just finished their preclinical courses in anatomy, physiology, pathology, and bacteriology had an intensive course of three hours a day for twelve days, during which they reviewed the essential functional anatomy of the different lesions of the extremities and spine. The common skeletal lesions of these regions were then shown. The students were taught to apply to each other simple, practical, and, as far as possible, standardized apparatus for the treatment of these lesions. The avidity for such a course was enormous. A student who applied to a fellow, and had applied to himself, and then removed, an adhesive plaster strapping, or a plaster-of-Paris bandage, appreciated at once and permanently the sensation of the surgeon and the sensibility of his patients. Thomas splint drills were conducted in rivalry of teams as in war surgery. In the third year clinical lectures and fracture clinics were held for small sections totalling twelve to eighteen hours. The fracture service of the Massachusetts General Hospital, to which reference had been made, lent itself with peculiar facility to such teaching. They had come to feel that, at least in their country, for the moment, there was a distinct advantage to be gained by the establishment in great hospitals of fracture services supervised by surgeons especially interested in fractures, and therefore especially skilled in the treatment of these lesions. All the house-officers and pupils and nurses in training should serve for stated periods on such a service. Whether this service was under the direction of the general or orthopaedic surgeon seemed of no moment. They believed that a surgeon most keenly interested in bone and joint extremity surgery, if he possessed equal ability and devotion, would probably obtain better results than a surgeon whose chief interest was absorbed by abdominal, brain, or urological surgery. The utmost harmony existed in the service with which he was familiar, between the group of general surgeons and the group of orthopaedic surgeons who comprised the service. They felt also that when such a service had been organized it was advantageous to have the fracture cases segregated in one or two wards. The nursing force became much more useful if its attention was thus concentrated. Apparatus was much more uniformly efficient, and for teaching purposes the advantages were obvious. They felt that the surgeon whose interest lay elsewhere ought no longer to turn over his fracture cases to his house surgeon until that

house surgeon had had adequate instruction and experience. It was becoming a serious matter, with them, for him to do so, for not only was his moral responsibility to his patient thus unsatisfied, but the fulfilment of his medico-legal responsibility might well be the subject of question, and sometimes of embarrassing inquiry. Mistakes were always instructive, and Dr Osgood thought that they might count on enough continuing to occur to serve the purpose of the student, but attention should surely be attracted when one of the leading surgical teachers in America found it necessary to write as follows against the teaching of fractures: "I feel that the teaching of fractures may be emphasized by analysis of unsatisfactory end-results. Because of the nature of our clinic we have considerable material of this kind." They certainly owed to their patients the best they could give. They could hardly hesitate to initiate this much-needed reform deterred by the fear of more specialism, for with them it had brought about less specialism, and had created a much wider interest in these neglected cases. It had added a reagent, which had dissolved some of the precipitate thrown down by the specialities, and made it again a part of the general solution. This should surely be the aim of the orthopaedic surgeon, whose speciality was not a speciality of anatomy, but what might be called a speciality of function. By constantly striving to add a solvent and turn back into general medicine and surgery all that they were willing, to appropriate, they would lose their own soul—in order eventually, it might be hoped, to find it.

Mr H. Warr (Edinburgh) said that though they might differ as regards the remedies he was sure they all agreed that the results of the treatment of fractures in their public hospitals were not satisfactory, and that the clinical instruction in the treatment of these injuries that their students received was inadequate. These facts were in themselves sufficient to make that discussion of great importance, but arising out of them there was a far greater question—namely, the lines along which the organizations of the premier hospitals of this country were to evolve. What was to be the future of specialization in surgery in all its branches? The organization of the treatment of fractures and the clinical instruction of the student in this branch of surgery were associated but not coequally interdependent. Their primary duty as hospital surgeons was to the individual—to see that he received the best possible treatment, and the plea that in obtaining it the instruction of the student would suffer could never be entertained. They might safely assume, however, that what was best for the patient was the best form of instruction for the student. It was fortunate that the question should be raised in connexion with orthopaedic surgery. The majority of the fractures dealt with were met with in the wage-earning class, and those who saw much of the after-effects of injury realized that the problem of the maimed industrial worker was serious and pathetic. To the individual it so frequently meant misery at home and his ultimate gravitation, often through a course of weary legal bickering, into the category of "suitable for light work," which was reached after experiences which not infrequently led to his moral, physical, and mental deterioration. To the employers it was also a serious problem from the economic standpoint, the financial burden which it imposed being one which still further increased the expense of production and impaired industrial efficiency. It was not surprising, therefore, that in this country, and in the United States of America, as Dr Osgood had mentioned, they were taking an increasing interest in this branch of their work. In the spring of 1921 Mr Wade had delivered a British Medical Association Lecture to the Fife Branch on the influence of the war on the modern treatment of fractures. He then quoted certain facts gleaned from a large employer of labour on the economic aspect of the treatment of fractures in the industrial world. Before he came to the present meeting he had asked the same employer what approximately was the cost of a malunited fracture of the femur, and he replied that it might be put down at anything from £500 to £1,000. To the individual and to the employer, therefore, the issue was a serious one, and, as was only to

be expected in such circumstances, there was already evidence that the question was being looked into by some of them, not only from the humanitarian standpoint, but also from that of sound, efficient business organization. Both masters and men realized that the efficient treatment of the injured was a sound business proposition, and he was sure they would be willing and prepared to give good financial support to any scheme that promised to bring this about. A commission of inquiry into this question would be warmly welcomed. Such an inquiry would, first of all, deal with the front-line service of industry, and he was convinced it would be satisfied with the manner in which it was now being carried out. The first aid stations and treatment rooms in the mines and foundries were good and the work ambulances now available were abundant and excellently equipped. The Thomas splint was being more and more employed and little organization was further required to make it as readily available at the coal face or in the foundry shop as it was in the front-line trenches, there was nothing to prevent the ambulance orderly becoming as good at applying it as he or his brother was when a regimental stretcher bearer. The interesting part of the report would be when it came to deal with the arrival of the patient at their hospitals. Mr Wade feared that here the criticism would be most severe and the recommendations most drastic. It had been asked why those who knew so well what was achieved in the treatment of fractures during the war had not carried on that high standard of efficiency. When that suggestion was made by such an authority as Sir Robert Jones, Mr Wade said that he would plead with him that they felt his criticism severely for when they returned home to civil life full of enthusiasm as all did they were keenly anxious to do so, but found it impossible to carry out at home the same system of organization as in the war hospitals. The circumstances were so entirely different. As hospital surgeons they had individual independent charges and were grossly overworked. The assistance provided was totally different from that obtained in the hospitals in war time. With the exception of the assistant surgeon and what in his school was called the clinical tutor, whose services, like theirs, were limited to a few hours in the day, all the other members of the staff were essentially unqualified men in training. Was it surprising, therefore, that where fractures had to be treated, observed carefully from hour to hour, and corrections and adjustments made from day to day, the hospital surgeon had sought other methods that would permit of these injuries being dealt with in a manner which would dispose of the problem once and for all, as by open operation in the operating theatre, or the application of plaster under his direct supervision, and achieve finality? If these methods had provided the perfect result that at one time was anticipated, there would be no question for them to discuss. Unfortunately, the contrary had proved to be the case. The cases that could best be treated by open operation or by the immediate application of a plaster splint were few in number and seldom met with. What, then, was the solution? Mr Wade saw no other hope than that an expert with the necessary knowledge and time available should be given the responsibility of supervising all these cases, and for preference have complete and entire charge of them all. This meant the establishment in all the large teaching hospitals of special orthopaedic departments with the necessary beds, under the charge of an orthopaedic surgeon. He saw only one criticism that could be justly lodged against this proposition, and it was the ultimate division of the practice of surgery into many individual specialities, for after the creation of an orthopaedic department there must follow the establishment of a similar neurological charge. Neurological surgery, likewise, would become an independent speciality. This arrangement would certainly benefit the patient immensely, for the men who would undertake this work would at first be experts in their own speciality and also have had a long course of training in general surgery. The only fear he had was that it should be permissible for the recently qualified brilliant house surgeon, attracted by the glamour and fascination of orthopaedic surgery, neurological surgery, or some other specialism, to devote immediately his entire time to specializing in this branch alone, and in it he undoubtedly

would become highly qualified. A narrowed outlook, however, meant a parochial mind. The limited liability surgeon was a dangerous person. To avoid this, Mr Wade considered that it was essential that no orthopaedic or other specialist should be appointed to the entire charge of such a department until he had served a long apprenticeship in general surgery, or, better still, if he was a younger man, be associated with a larger surgical charge in which he would be brought in daily contact with the practice of general surgery, and preferably participate in this work to a limited extent. They might advocate such a scheme of reorganization, but at first they would not believe it. They who were members of the staff of teaching hospitals were proud of their great traditions, but realized that to effect any modification in their scheme of organization, which sometimes had stood unchanged for centuries, was naturally very difficult, and could only be brought about slowly, gradually, and step by step. When this was the case he would recommend to their consideration the system that some were endeavouring to introduce in the hospital to which Mr Wade belonged. They had each their small independent charge, but while continuing to practise general surgery in that post they had endeavoured with some success to qualify themselves more particularly in one department of surgery. They had done so, not for themselves alone, but to assist their colleagues in dealing with this branch of their work, and in their turn they received help in other directions. Their junior colleagues had specially benefited by this arrangement, and certain of them, while continuing to participate in the ordinary duties of the ward in the practice of general surgery, were devoting their time to the intensive study and practice of certain specialisms in which they were rapidly becoming very well qualified. The criticism had been advanced that the creation of special departments in general surgery would interfere with the efficient teaching of the undergraduate student. Mr Wade did not think so, and certainly it would greatly improve post-graduate instruction. In view of the rapid and widespread extension of the practice of surgery in recent years the importance of this was very great. It was to the larger teaching hospital that they had to look for the instruction of those who in cottage hospital and elsewhere were called on to do their surgical practice. They came to the larger hospitals expecting to find these men, not only qualified to do their routine work efficiently, but also to observe the best and most recent practice in all departments. So far they had not failed to find this, but if the teaching staff of these institutions was to continue to meet their requirements it must move with the times and further enhance their knowledge, which could best be done by further specialization in the manner suggested. He advocated, therefore, that as far as possible where special departments were being created they should be attached to a general surgical charge, and that the junior members of the surgical staff in such special departments should continue their training in general surgery by giving a limited amount of service to the department of general surgery as well. Out of this system, he trusted, there would evolve ultimately the complete surgical unit, maintaining within it all the departments of surgery, including gynaecology, the workers in which should meet together daily observe each other's work frequently, and the junior members of their respective staffs should mutually co-operate and interchange their posts. By this means there would be produced the better trained specialist, and one in whom the decision to specialize in any branch of surgery was arrived at after a period of sound and broad general training and at an age when, after mature reflection, he and his friends had come to the decision that by natural aptitude and instinct he was pre-eminently qualified for the practice of that specialty.

Mr HARRY PLATT (Manchester) said that he spoke in this discussion in the first place as a surgeon who for the past eleven years had had the good fortune to control the whole of the fracture material in a general hospital, and, secondly, as one who, beginning as a general surgeon, had under no compulsion come to restrict himself to orthopaedic surgery. According to the distinction made by Mr Call he must therefore accept the title of specialist. The organization of the fracture department in his own hospital

had already been described some years ago in the *Lancet*. It comprised an out-patient fracture clinic and an in-patient segregation of fracture patients under the control of one unit. It had been interesting to observe the influence of this department on the attitude of a succession of surgical residents. Their residents, who had been drawn from many different schools, for the most part had become general practitioners. Almost without exception they had acquired a love for the treatment of fractures and confidence in their ability to handle the ordinary everyday cases. Sir Robert Jones had dealt with the historical reasons for the general lack of interest in fractures at the present day. They must all recognize that before the Listerian revolution, and indeed in the generation which saw the widespread adoption of antiseptic methods, the treatment of broken bones and allied disabilities loomed large in the daily routine of the hospital general surgeon. They must also believe that the surgeons of that generation obtained very good results in their fractures, even though denied the aid of modern physiotherapeutic methods in after-treatment. But with the advent of abdominal surgery, the surgeon acquired a new orientation. During the past twenty years the commonplace injuries and disorders of the extremities had gradually receded into the background in the surgery of the general hospital. It was true that the great war had brought a rude awakening, but it would seem that its lessons—which, as Sir Robert Jones had said, were concerned with the value of organization rather than with mere advances in technique—had been forgotten. It could not be said that the general handling of fractures in hospitals, and the teaching of the undergraduate in the treatment of such common disabilities, brought great credit to British surgery. Furthermore, it was clear that the general practitioner of this age did not approach a fracture with the same confidence or skill as his predecessor. Both parties in this discussion appeared to agree that reform was needed. In his own judgement the only solution was contained in the principles of the scheme which Sir Robert Jones had put forward. Mr Gask viewed this scheme with misgivings, and he had raised, in no spirit of hostility, that old illogical lack of sympathy which still obtained between the general surgeon and the special surgeon. They did not question the sincerity of Mr Gask's views, and his quixotic defence of a losing cause compelled admiration. Mr Gask was opposed to the educational control of students by "specialists" and to the segregation of in-patient fractures under the sole charge of the specialist. The specialist referred to in that meeting was of course a euphemism for the orthopaedic surgeon, who was represented as an individual whose *raison d'être* was the possession of special skill in a limited field, and who was interested only in the training of future "specialists." This was a most unfortunate misconception. The special surgeons in that meeting were in no way different from the general surgeons in their early training or early efforts to traverse the whole field of surgery in hospital practice. Most of them had been reluctant to give up any branch of surgery. They were impressed, however, by the fact that the working hours of the day were limited, that life was short, but art was long, that there was little time to acquire knowledge which might, perhaps, contribute something to the intellectual currency of this and a future generation. For such reasons they had preferred to limit themselves to one great surgical field—which they hoped would remain an essential part of general surgery. In this field, of which fractures were an integral part, they stood out in contradistinction to the ordinary general surgeon, not as possessed of special skill, but by reason of their knowledge of its literature, its foundations in physiology and pathology, and not least its philosophy and relation to medicine as a whole. These attributes did not render them unfitted to take a full share of the direction and educational control of the student. The student would gain his inspiration from the best man, whatever his label might be. There could be no legitimate objections to the principle of segregation in surgery. Most of the great clinical advances had come from what might be called "massed production"—namely, the concentration of material in the hands of the few—witness the abdominal surgery of Leeds, the cerebral

surgery of Johns Hopkins and Harvard, the orthopaedic surgery of Liverpool, and so on. If fractures were to be segregated it was essential that they should be under the control of surgeons of full rank. In a very big hospital where the fracture material was abundant, a dual control of a general surgeon interested in fractures and prepared to give the necessary time to the work, and the orthopaedic surgeon of the hospital, working as equal directors with a full term of assistants, formed the ideal scheme. In a small hospital the allocation of the fractures to the control of the orthopaedic surgeon was likely to be the best arrangement. No progress could be expected if ambulatory fractures only were segregated, or if segregation was adopted with a junior surgical officer in control, or worse still under one who was not a surgeon at all. The facilities which a proper segregation of fractures afforded for student teaching were unique, and obvious to anyone who had experience of the working of such a department. If this plan was adopted widely, it meant a reorganization of the present undergraduate surgical curriculum and the restoration of the common disabilities to their rightful heritage in surgical teaching as a whole.

Mr H. H. SAMPSON (Birmingham) said that it must be borne in mind that probably one half of the fractures in this country were treated at home or in cottage hospitals by the general practitioner. It was most important that he should have had the opportunity of dealing with these cases during the whole course of his surgical training. It was impossible to become conversant with such a wide subject in a short concentrated course in a special clinic. The treatment of a single fracture might occupy many months, and it was essential that the student should be able to observe such cases during the whole of their treatment. Unless he could watch the progress of particular cases it did not seem possible for a student or house-surgeon to gain the necessary knowledge and experience to enable him to undertake their treatment when he was in practice. With regard to the organization of treatment, it must be remembered that there was an enormous number of cases to be dealt with. However many beds were provided there would always remain a large majority of ambulatory cases to be treated as out-patients, and the treatment of these could not be entirely entered for by a fracture clinic. Perhaps the most potent influence on the subsequent course of a fracture was brought to bear when it first presented itself for treatment, maybe in the middle of the night, in the casualty department of a general hospital. Now was the moment for their fracture specialist. Whatever organization was provided the initial treatment was usually carried out by the house-surgeon on duty in the casualty department, and it was on the wisdom of this officer that the ultimate fate of the fracture largely depended. It frequently happened that daily observation controlled by repeated radiographic examinations and perhaps resetting under anaesthesia on more than one occasion was necessary before a case was fit for transfer to the fracture clinic. This work could only be undertaken satisfactorily by a surgeon who attended daily in the casualty department. The number of fracture cases requiring admission to the wards under an improved scheme would be greatly increased. All cases which did not proceed satisfactorily in the out-patient department, difficult and doubtful cases, and such fractures as those of the lower end of the humerus, would require greatly augmented in-patient accommodation. As regards teaching, it would accommodate itself to the improved conditions of treatment. The increased care and attention which fractures would receive was bound to attract the attention of a student from his earliest days as a dresser. He would realize from the outset of his career how large a part the treatment of fractures would play in his future work as a general practitioner. When the student became a house-surgeon he would be better equipped to deal with fractures and more interested in the subject. Every house-surgeon who entered practice would have to cope with fractures, and it was of paramount importance that he should possess long and continuous experience of this class of work. Thus throughout his surgical training the future general practitioner would

be meeting with all varieties of fracture, and would have ample opportunity of gaining practical experience.

Sir Robert Jones and his school suggested that improved teaching and treatment could only be provided by a self-contained department carrying wards and out-patient clinic and staffed by special officers. The staff which he enumerated would be quite inadequate for the maintenance of a continuous day and night service such as would be required at a large general hospital. Unless such a service was provided the initial treatment must be left to the casualty house-surgeon, and it was the initial treatment which had the most profound influence on the subsequent progress of the case. The out-patient fracture clinics had special difficulties to contend with. Mr Sampson had consulted the surgeons who conducted the fracture clinics at his own hospital. Ninety to one hundred patients presented themselves at each clinic. It was obviously dangerous to the patient's welfare if the splints were removed before he was in the presence of the surgeon, therefore much delay occurred with every case that was seen. Careful examination and reapplication of the splints consumed more time. In practice it was found necessary to hand over much of the important work of the reapplication of splints to assistants. Officers in charge found that it was impossible during the rush of the clinic to give adequate consideration to any difficult or unsatisfactory case, and they were in the habit of making a special appointment for such work. The fracture clinic served as an excellent policeman, controlling the progress of the uncomplicated case, it did not intrude the treatment and it did not provide the opportunity for special consideration and treatment of difficult cases.

Mr Sampson had already pointed out that a short course of demonstrations on the subject of fractures would not suffice. Such a scheme could not include the handling of individual cases and the valuable teaching provided by the daily observation of their progress. The ordinary house-surgeon would not get any experience in the treatment of fractures, this might be disastrous to a man who might eventually practise in a district remote from a large surgical centre. He was not sure that sufficient stress had been given to the importance of securing trained auxiliary services—a splint maker who was available at all times to be instructed personally by the surgeon, nurses who understood the principles of treatment, were competent to adjust suspension apparatus to the patient's comfort, and to carry out necessary attentions without disturbance of the injury. At his own hospital there were two accident wards into which all male fractures were admitted. The sisters and nurses became conversant with the methods of treatment, and there was an expert mechanic and a carpenter to construct or modify apparatus. All out-patient cases were referred to a fracture clinic which was in charge of a surgical casualty officer. This system worked well and had undoubtedly improved the standard of treatment, but owing to want of space it was impossible to hold the fracture clinic during the busy hours of the day when the out-patient dressers were attending the hospital. Students were encouraged to attend the fracture clinic, but compulsory attendance could hardly be enforced until increased accommodation enabled the clinic to be held during their routine hours. In this particular case, then, segregation had improved the treatment but hindered the teaching. Situated in a great industrial area it was not surprising that the number of fracture cases was considerable. There were fifteen hundred new cases attended the fracture clinics during the year, and the average attendance at each clinic was between ninety and one hundred.

Mr Sampson suggested the following scheme of organization. All fractures requiring in-patient treatment should be admitted to special wards with an accommodation greater than any reasonable demand. The reserve of beds need not be kept empty, but should be used as far as possible for accident cases. The sisters in charge should be carefully selected and should have previous experience of the work. The nurses should be specially instructed in the details of nursing fracture patients and must understand the mechanical principles of the apparatus employed. The services of a trained mechanic and carpenter were essential. The beds would be divided equally among the surgical staff.

One surgeon, preferably on the junior staff should be appointed to exercise general supervision of all the fracture cases, to instruct house-officers and students in the methods of treatment, and to take full responsibility for treatment upon request by the surgeon in charge of the bed. Instruction and practical experience in the treatment of fractures would still form part of the in-patient dressing of every student. He would have the advantage of observing daily progress and of assisting in the application of apparatus. Clinical lectures on the principles of treatment could be given from time to time by the surgeons specially interested in the subject. One or two of the surgeons would probably show special inclination and aptitude for fracture work. They would lead the way in trying new methods and estimating the standard of cure. Methods of proved value would inevitably spread through the sister and house-men to the other surgeons' beds, with consequent improvement in treatment. Between the firms there would probably be keen rivalry fostered by house-surgeons and dressers, with the result that any old methods which were bad would rapidly drop into disuse, and new methods which were good would soon become incorporated in the practice of the hospital. The cases which did not require in-patient treatment would be referred to a fracture clinic under the direction of the specially appointed surgeon. The surgical casualty officer and the casualty house-surgeons could attend this clinic and they would have skilled assistance, which might be supplied by the special wards, the out-patient dressers would attend and receive instruction from the casualty officer. It was perhaps unnecessary to emphasize the importance of adequate radiographic assistance, both in diagnosis and treatment. Co-operation with the massage and electro-therapy departments was a vital necessity. Fractures should have a first claim on the attention of those auxiliary departments which were apt to be overworked and overcrowded. His conclusions were that increased accommodation and improved organization were necessary for the advancement of treatment and teaching. Students should have continuous experience of fractures during the whole of their surgical training. Every house-surgeon must have the opportunity of learning how to treat fractures.

Mr H. A. T. FAIRBANK (London) said he was in the fortunate position of being in charge of the fracture clinic in the general hospital to which he was attached. When considering reconstruction and the reorganization of the work of the hospital some six years ago, the surgeons came to the altruistic decision that the fractures should be handed over to the orthopaedic department. His experience of that fracture clinic convinced him that Sir Robert Jones's views were correct. All agreed that such segregation led to greater efficiency in treatment and thus benefited the patients. He also believed it benefited the student. More could be learnt in an afternoon spent in a fracture clinic, where most types of fractures could be seen gathered together, than by months of attendance in the general surgical wards and out-patient departments when the fracture cases were not segregated. Standardization of splints and simplification of methods were of the greatest benefit to the student. He admitted the difficulty of getting students to attend special departments; they always preferred to go to the general medical and surgical clinics. What was required was better organization of the working hours of the student, and it was not necessary to sacrifice the patient for the benefit of the student. With regard to splints, he thought wood should be used rather than metals, as the latter interfered with x-ray examination, which was so essential. There were exceptions, of course, such as the Thomas knee splint. The clinic of which he had charge was visited once a week alternately by the junior orthopaedic surgeon and himself. The former was also a general surgeon—a very important fact. Each term, in addition to the surgeon, consisted of a casualty officer, the house surgeon attached to the orthopaedic department, and a sister, who was always the same person. He differed to this small extent from Sir Robert Jones in thinking that the casualty officer should be included in the team rather than another senior assistant. The casualty officers were the men who had to treat the cases on arrival at the hospital, and they were the officers to be taught if the patients were to benefit to the

greatest extent. These officers submitted their work to the surgeon for approval and criticism, and they gained enormously by this arrangement. This organization was to the student's advantage also, since it was in the casualty department that he must gain a great deal of his practical knowledge of the setting of fractures.

Professor A. W. SHEEN (Cardiff) said that this discussion was concerned with defects in the treatment of the recent fractures of civil life in their present-day teaching, hospitals and their remedy, linked with a consideration of how changes in hospital organization would affect treatment, and thereby the teaching and the future practice of students. They had heard of the advantages of the segregation of fracture cases under a special fracture team, what were the disadvantages? There was the danger that the isolated team, while very efficient in treating the fracture, might not be equally efficient in treating the patient. There must be considered the severe traumas, the compound fractures, the multiple fractures, the fractures associated with other quite different injuries, and the shock which was an accompaniment of all such emergencies. Often the first thing to decide was whether an amputation should be performed or not. There must be a knowledge of the treatment of shock, of blood transfusion, of the excision of wounds, of the treatment of infections, of the treatment of associated injuries, of the treatment of lung complications. If the head of the fracture team was an orthopaedic surgeon purely, then his other practice was largely non-emergency, rendering him less qualified than others to deal with these emergency conditions. Another disadvantage that he found came from his dislike of over-committed surgery, and from his opinion that a number of surgeons, each excelling in a different direction, should work together as a large team or surgical service. He advocated, therefore, the admission of fractures under a general surgical team of which a fracture surgeon (who might be an orthopaedic surgeon) should be a member. As there were usually several surgical teams in a hospital the fracture surgeon would work with all, or—as this would probably entail undue demands upon his time—it would be better for all the fractures to be admitted under one team, which then should have a larger number of beds than the other teams so that its beds for cases other than fractures might not be inadequate. He agreed that it was better for all the fractures to be segregated, although wards could not usually be given up entirely to fractures, since empty beds would be wanted for other emergencies. A fracture clinic for out-patients, of course, commanded universal approval.

Certain minor disadvantages resulted from fracture segregation. Treatment might become too stereotyped where there was not emulation and comparison between different teams. There was no rest from the "taking-in" of these emergencies as there was when they were distributed. A surgeon who was not called upon to deal with fractures in hospital treated them with less experience in his private practice. One segregation led to others, and multitudes of more or less watertight compartments were to be deprecated for many reasons. All this compartmenting seemed to incite to irregular practice, if they might judge from America, where osteopaths and chiropractors thrived. Work in large surgical teams, each containing, or commanding the services of, the requisite specialists, was his present ideal in hospital surgical practice. His own surgical unit team consisted of himself as a full-time officer and three part-time assistants. They discussed and consulted upon all their cases, often before their students, and grouped various classes of cases under one or other of them. The fractures had been his own special care. The other teams in the hospital treated their fractures, and one of the assistant surgeons held a fracture clinic once weekly for out-patients. It was his hope that in time the fractures would be under one of the general surgical teams in special beds, and that a fracture surgeon would be one of this team. He asked Sir Robert Jones what arrangements obtained in the hospital treatment of fractures in the two places—Liverpool and St Thomas's—with which he was most associated.

Professor Sheen did not attach much importance to the suggestion that they were adding to an already overburdened

curriculum by segregating fractures. If this was done in the way he had just advocated fractures would be largely taught in the ordinary dresser's work. He did not agree with the suggestion of saving the student's time by his not watching operations which he was never likely to perform. It was only by studying a case at the bedside and in the operating theatre that a student could learn early diagnosis, and so be able when in practice to send his cases for operation early. Take the gall bladder for instance: the inaugural symptoms were demonstrated in the ward, and the early disease in the theatre. Instances of this kind could be multiplied indefinitely. Only by repeated ward and theatre demonstrations should they produce practitioners who would send their patients in an early curable stage or save them years of suffering. Now the student was to see and take a hand in the diagnosis and treatment of fractures, and thereby he was to learn. A disadvantage to him was that he would take less of a hand when the fracture team was evolved with its permanent highly trained assistants. Diagnosis he could and must acquire, but what about ability to treat? Treatment was often complicated and difficult. Fractures cropped up comparatively infrequently in the majority of practices. The practitioner was not in himself a team of surgeon, assistants, nurses, and mechanics, with all the elaborate material required. Whatever might be said about the universality and simplicity of the Thomas splint, it was often wrongly applied by the relatively inexperienced, when it was worse than useless. Thomas's splint was often associated with complex modifications and additions, and it could not have satisfied many judging by the innumerable other types of splinting and special splints that had been devised and used. He considered that certain fractures could never be treated effectively except by proper fracture terms, and he advised that the machinery of practice should be altered so as to bring the injured individual whatever class of the community he or she might belong to, under the care of such a team. Such fractures were most of those of the lower extremity and those about the shoulder-joint. He would concentrate on teaching the student the treatment of elbow fractures, particularly in children of forearm fractures, of Colles's fracture and of Pott's fracture, counselling him when he was in practice to send other cases and all cases that appeared rare and difficult to a suitable institution. In these days of motor ambulances and perhaps soon, in places like India, of ambulance aeroplanes, this should not be difficult.

Next with regard to the early sending out of fractures from hospitals which Sir Robert Jones deprecated, here indeed many of them were in desperate case. In his own hospital half the surgical cases admitted were emergencies, the waiting surgical list numbered considerably more than a thousand. Beds must be found. Consciously or subconsciously he might have been influenced by this necessity, but anyway he had pinned his faith to plaster-of-Paris for the majority of fractures admitted. They had used Thomas's splint often, they had used pins and callipers, they had operated to imbricate and to plate, but plaster remained the sheet-anchor, and he was perhaps still influenced by the excellent Croft's splint taught so well in his student days at Guy's. He was accustomed to give his students a textbook on the treatment of fractures in three words: (1) anaesthesia, (2) reduction, (3) plaster. Immediate full surgical anaesthesia. Reduction which was not a mere perfunctory attempt but forcibly manipulative and aided by apparatus, the Hawley table—which was only the bench of Hippocrates—being commonly used for fractures of the lower limb. Regarding the plaster he expressed his indebtedness to a one-time association with the Military Orthopaedic Hospital at Shepherd's Bush, where he learnt of the plaster, mushin, and wadding, which were the best, and which they used. Narrow-grooved metal strips were incorporated as required in the plaster. From Shepherd's Bush also came to them three years ago the sister who was head of the plaster department there, and who had been invaluable in theirs. Besides dressers attending, he attached other students specially to the plaster department as their opportunities permitted, and they welcomed the training and profited by it. A crisis in both planes

checked the results. If the position was bad, in anaesthesia, manipulation, and plaster were repeated. Making the plaster cases bivalve or windowed permitted dressing of compound fractures, and an opening plaster case permitted early massage. Some septic compound fractures had healed at once when sewn up and put under plaster. He was inclined to think that joints did not usually contract adhesions simply from immobilization. He showed a photograph of a lad who had fractured the neck of one humerus, the upper part of the shaft of the other, and the left tibia and fibula. He was treated in closed plaster, and was now back at full work as a collier.

Finally, he had not shirked the issue. Recently he had sent reply paid letters to all the patients with fractures of the long bones of the limbs (about 120) treated by the surgical unit since its beginning—namely, from October, 1921, to December, 1924. The majority either responded to the invitation to come for inspection or sent replies stating their condition. The unit reports would contain an analysis of these observations, which generally were not unsatisfactory. The inspections were most illuminating and were helpful for future work. Students attended and assisted. Such "follow-ups" were a feature of fracture organization which he considered of great importance.

Professor Slicen summarized his recommendations as follows. In organization, a "fracture surgeon" with proper staff and material to work with a general surgical team or teams, out-patient fractures, under such a fracture surgeon, institutional facilities for treating fractures for all sections of the community. In teaching, the learning particularly of diagnosis and of "first-aid" treatment, the appreciation of those fractures which required immediate institutional treatment, and a thorough knowledge of the home treatment of certain other fractures. In both organization and teaching, the establishment and display to the student of a complete "follow-up" system. He desired to express his great indebtedness to Sir Robert Jones for pointing out the defects in the treatment of fractures and for inciting them to study the causes of such defects and to find remedies.

Mr. C. MAX PAGE (London) said that after hearing the opening observations on this subject he felt that the points of divergence between the speakers were really narrow. Perhaps this was due to the broad minded and liberal spirit in which Sir Robert Jones and Mr. Cash had approached the problem, the practical difficulties which must be used being thereby in some measure obscured. At the end of a long, over ground already dealt with by other speakers, he would put forward his own views of the situation. It appeared to be generally accepted that the main thesis—namely, that the average present treatment of fractures in this country was unsatisfactory—must be accepted. Personal and local reservations to this view there were, no doubt, but the fact could not be escaped that most of them saw, if they did not commit, avoidable mistakes in the handling of fractures both in hospital and outside practice. Perhaps Sir Robert Jones had allowed them a little with a blacker picture than the facts justified. He suggested that there had been little or no improvement in practice of this character during the last ten or twenty years. It must be recognized that in his position he saw a very large number of the failures which did occur, and on this account might be excused a somewhat jaundiced view of the situation. Some of his evidence on the point must be regarded as rather out of date. Mr. Page certainly did not think there was any ground for general hospitals who were satisfied with two inches of shortening after a fracture of the femur, but rather that there had been a definite and general advance since the war in the treatment of fractures, and he knew that most of the teaching hospitals in London had made efforts to improve matters. In considering the present position it must not be overlooked that a certain proportion of the bad results seen to day came from the hands of those whose medical education dated from before or during the war. These reflections might perhaps help them to avoid blame in the matter, and at any rate lead them to investigate closely the remote as well as the immediate results of some of the experiments in organization which had been initiated, before completely changing current

hospital arrangements. Accepting the general view that the organization for the treatment of fractures in this country was far from perfect, one might most usefully concentrate on the consideration of the practical remedies which were advocated to correct the defects. Sir Robert Jones had brought forward the outline of such a scheme. His proposals on paper appeared so attractive and promised such efficiency that one hesitated to criticize them. For the non-teaching hospitals Mr. Page would let them stand, but for teaching institutions he thought they possessed definite weaknesses. In outlining their conduct for the future in this relation they should look very carefully to the effect of any scheme on the education of the medical student. The fully organized and specialized unit that Sir Robert Jones postulated could not fail to handle fractures up to a very high standard, but was there not a danger that its adoption would add one more pigeon hole to surgery—another specialization within a specialty? Would it not remove the student from the close practical contact throughout treatment which was essential if he was to obtain a proper grasp of the principles of treatment? They had most of them seen the development of specialism and appreciated the justification for its existence for certain groups of cases. The basic reason for the segregation of any branch of surgery into a special department was founded upon one of two factors, the first of which was the need for the use of special apparatus requiring expert handling and long experience for its proper application. The subjects of ophthalmology and laryngology were examples of specialties which had been established for this reason. The second reason was the existence of a sociological demand for the group treatment and supervision of those suffering from certain ineffective processes, such as tuberculosis and venereal disease. Specialization of this kind was undoubtedly of benefit to the community, though it would probably be generally admitted that it prejudiced the education of the medical student in those subjects. Should fractures be added to the list on either of the above grounds? Certainly not on account of the first—the treatment of the majority of simple fractures was a straightforward carpentering job which only demanded common sense, a knowledge of the reactions of the body to injury, and practical experience. The use of x-rays had so far simplified diagnosis and the control of treatment that it might be said that apart from radiology, no really specialized experience was required. It remained to consider how far the second or sociological reason for specialization held in this case. At first it might appear a valid one, but it must be appreciated that a large proportion of fractures in the country must be treated by the medical practitioner. The same was true of mining conditions abroad and in the services. In the event of war they did not only want to have fifty highly trained men to stay at home in charge of hospitals, they should want thousands of men of average competence who had practical knowledge and the self-reliance begotten of experience to handle fractures and injuries away from expert assistance. He did not think that teaching afforded by a special department would provide them with sufficient men of this type. In respect of pre-graduate study, the general effect of a special department was to make the subject to the medical student an academic one. He might show up very well on paper, but was a poor performer when left alone in sole charge of a case. He did not wish his remarks to suggest that he was against any form of segregation of fractures. He thought that a measure of segregation in after-treatment both for fractures and minor injuries was essential for a large hospital, but he would stress the point that all fractures should pass through the casualty department in the first place. Here they were seen together with other injuries by the student during his term of office as a dresser. The problem of supervision in a general hospital, if his point was conceded, was a different one for the out-patients and for those admitted. As Sir Robert Jones had so plainly put it, the essential factor for success was that the officer in charge should be experienced in this type of injuries, and keenly interested in their treatment. Mr. Page would prefer him to be a general surgeon, but if the general surgeon had not the time or inclination to deal with the problem then the orthopaedic surgeon should clearly be

given a chance of taking his place. But he did not think that the suggested clinic should become an integral part of an orthopaedic department. It must not be overlooked that patients the subject of a fracture might have internal injuries or suffer from infections which could not be properly handled by a specialist. He thought that the important point in any segregation in the after-treatment of fractures was that close co-operation should be established between the officer in charge of the physiotherapeutic department and the surgeon primarily responsible for the treatment of the case. He feared that his remarks might in effect appear to be destructive rather than constructive. The subject was, however, a very important one, and one which, if it was to be dealt with effectively, demanded considerable reorganization of the surgical work of a general hospital. He felt that there was a possibility that, in changing their methods so as to gain an immediate and obvious improvement in detailed treatment, they should only succeed partly, owing to a failure in the education of the future rank and file of the profession in respect of the condition under consideration.

Mr. McADAM DEELES (London) said that he was in accord in almost every detail with Mr. Gask. For the sake of the fracture patient at the moment in the hospital he was willing to concede that it might be better for him or her to be under an orthopaedic surgeon, but he was certain that for the general practitioner and for the general public it was better in the long run for the immediate patient in the hospital, and for the future fractured bone in the country, for the patient to be in a general surgical ward. At the outset it was a truism that the greater number of fractures were not treated in hospitals to which medical schools were attached, but in smaller country and cottage hospitals, in out-patient departments, and even in private hospitals and private houses. How then could they best train the medical practitioners who had to treat these multitudinous cases of fracture? One of the chief difficulties of teaching the treatment of fractures if they were segregated was that it was certain that from every batch of students some would miss this special training chiefly because the time of the curriculum did not admit of the arrangement for this particular specialty. Secondly, there was a very important point, which was that the student must be taught methods of treatment which he could use in private practice. When the general practitioner was faced with a fracture in private practice, his first thought was, What was the simplest and yet the best method of treating the particular fracture. Mr. Deeles had always personally advocated that every student should have a practical knowledge of a good recognized method of treating a fracture of every one of the chief bones of the skeleton, and he considered that all general surgeons should have sufficient practical acquaintance with such treatment so as to be competent to teach the average student adequately. He was sure also that it was important that every nurse should have practical experience of fracture nursing. Finally, he believed that if all fractures were placed under orthopaedic surgeons, it would mean at least tripling the beds at the disposal of the specialist, and probably doubling the number of orthopaedic surgeons.

Mr. GWYNNE WILLIAMS (London) said that though described as an orthopaedic surgeon for the purposes of the discussion he was a general surgeon, at least he thought he was until he had heard what terrible results in fracture cases were produced by the latter class of surgeons. He was optimistic enough to believe that Sir Robert Jones had painted the picture a little blacker than it really was, no doubt owing to the fact that the failures were brought to him from a wide view. Mr. Gwynne Williams also saw bad results, some of which were not his own, yet he had thought that treatment generally was improving. The problem of teaching the treatment of fractures presented three different sides. In the case of students it must be emphasized that the treatment of a fractured limb was very different from that of such diseases as appendicitis, in which diagnosis and operation were the most important, and all the essential treatment was, in the majority of cases, finished in a few days. The treatment of a fracture

extended over weeks or months until the patient had completely recovered and was fit to work. He therefore preferred that a student should take charge, under supervision, of a fracture throughout its treatment so that he could learn how necessary was continuous care of the case. In the present arrangement of the curriculum this could only be done satisfactorily during the period of clerkship, he therefore thought it desirable to return fractures in the general wards under the surgeons for whom the students dressed. It was generally admitted that in the second-year appointments the student did not come into that intimate contact with the case which was necessary if the treatment of a fracture was to be thoroughly learned. The second side of the problem was the hospital resident. He felt very strongly that no house surgeon should be deprived of the opportunity of treating fractures, there was no other period in the education of the man or woman who was going into general practice during which he or she learned more of the purely technical aspects of surgery (and the treatment of fractures was essentially technical), since the stimulus of responsibility deeply imprinted the lessons to be learned. If fractures were segregated still fewer doctors would have had experience of their treatment. It had been said that the general surgeon deprived his house surgeon of the opportunity of treating fractures by discharging them admittance and hastening their discharge in favour of abdominal and other cases, but he found that the difficulty was to persuade the resident to take in fractures and keep them in for efficient treatment, for the average house surgeon thought of surgery in terms of operations. Finally, there was the teaching of the surgeon, perhaps the most difficult part of the problem, for this he thought that there were advantages in segregating fractures, because although Sir Robert Jones had told them that the treatment was easy and that in the hands of experts even intracapsular fractures of the neck of the femur gave good results, yet Mr. Gwynne Williams had encountered many problems in the treatment of these and other difficult fractures. There was a large amount of work to be done in deciding on the best methods of treatment. For this purpose the surgeon required the material for investigation to be concentrated in order to work out various methods and to compare results. This method had been a great stimulus to thought and would inevitably further their purpose in obtaining better and better results, but he hoped that the treatment of fractures would be practised throughout as wide a field as possible in order that these two Sections might meet again, not so much to decide who should treat cases, but to discuss the technical methods by which difficulties might be overcome.

Professor ANDREW FULLERTON (Belfast) said that at the Royal Victoria Hospital, with which he was connected, fractures were treated by the general surgeons in the general wards. The teaching of the late Alexander Gordon, at one time professor of surgery at Queen's College, was responsible for the interest taken by Belfast surgeons in fractures for several generations. The inventor of Gordon's splint for Colles's fracture was an enthusiast in everything pertaining to fractures, and his influence was still dominant in the Belfast Medical School. Professor Fullerton believed that the teaching of fractures in Belfast was, on the whole, satisfactory. The cases being in the general ward they could be followed day by day and week by week by the clinical clerks, and their progress noted by the use of a travelling x-ray equipment. He took as an example of the work done in his own wards 70 cases of fractured femur treated during the last five years. 41 of these were of the shaft, and the remainder in the neighbourhood of the neck. In the 41 cases of fracture of the shaft there was an average shortening on eversion of less than a quarter of an inch. Students were taught that an inch of shortening was a disgrace, and that a patient who left the wards with a stiff knee as the result of a fractured femur was a disgrace. Of the 41 cases, 6 were plated and the rest treated by Thomas's splint, with the addition at the end of five weeks of the flexing iron to prevent stiffness of the knee-joint. His own results had improved since the war owing to the teaching of Sir Robert Jones, and especially to his association in France with Major Maurice Sinclair,

one of the most expert exponents of the art of treating fractures he had ever seen. The hospital arrangements in Belfast did not provide for a special orthopaedic department, and the responsibility for the treatment of fractures rested on his colleagues and himself, all of whom were general surgeons. He felt justified in saying that they had shouldered the responsibility, and in the circumstances obtaining in his part of the country had produced results which would bear a favourable comparison with those of other clinics.

He did not think the segregation of fractures in special wards was practicable in Belfast at the present moment, as the hospital with which he was connected could not accommodate them all. Many fractures were treated in cottage hospitals scattered over the North of Ireland by general practitioners. The training of these practitioners was a problem involving a good deal of responsibility, of which he and his colleagues were deeply sensible. Any practicable scheme which improved the teaching of fractures in his area would receive earnest consideration and support.

Mr R. C. LINSLEY (London) said that the subject was no new one. At St. Bartholomew's Hospital in 1642 a surgeon bonesetter was appointed to the hospital to set fractures, and a few years later an assistant had to be appointed. So that the hospital was a pioneer in this matter, although it had not kept up the organization. Mr. Eccles and other specialists had told him if Sir Robert Jones was advocating that all fractures should be placed under the care of an orthopaedic surgeon, but this was not so, he advocated that they should be placed under a surgeon who was interested in them, and in Mr. Linsley's experience many surgeons were not interested in them. Mr. Goss claimed that their duty to students was to teach fundamentals, surely the fundamentals of fracture treatment were an essential part of the knowledge of all medical men, far more important than the details of elaborate abdominal operations, which the student at the present day had to spend much of his time watching and recording. The specialist did not necessarily teach the student the details of his specialty, but by greater experience was more likely to recognize and emphasize the fundamentals.

Professor A. T. BAZIN (Montreal) said he had not been actively interested in the treatment of fractures for some years, but he was chairman of the surgical staff of the Montreal General Hospital and chief of one of the surgical services. Therefore, from an administrative point of view, he was keenly interested in both the treatment and teaching aspects of fractures. In 1919, after return from France, they established a fracture clinic—both in-patient and out-patient. Two young general surgeons were put in charge, both had had an experience with fractures, and both were keenly interested. There were two still more junior general surgeons as assistants and a house surgeon for the clinic. The out-patient fracture clinic was held once a week, and was largely of the nature of a follow-up clinic, the patients attending for supervision until function was satisfactorily restored. The department was not a watertight one. Fracture cases overflowed into the general surgical beds or vice versa, according to the demand. The chiefs of the general surgical services had supervision over the fracture cases, and at weekly surgical staff rounds these beds were included. Nor was there any regulation demanding that all fractures should be treated by the personnel of the clinic—either in-patient or out-patient. Nor did the members of this personnel limit their work exclusively to fractures. Thus they had achieved a very elastic arrangement in which there was segregation of fracture patients without narrow "specializing" on the part of the attending staff. Then, as regards results—and first treatment. In September, 1924, and therefore not for use at that meeting, there had been handed to him a report of the first five years' work. He spoke from memory, and would mention but a few of the salient features. In 2,000 cases admitted to the in-patient clinic there had been no cases of non-union and only three cases of delayed union. No patients had been "plated", in fact no plates were handled except in the removal of three for non-union, plated elsewhere. There had been no case of amputation for compound fracture, crushed limbs obviously

requiring amputation were admitted to general surgery beds. There had been a progressive diminution in the duration of hospital residence because of the adoption of ambulatory treatment in the later stages of treatment and the possibility of close and continuous supervision of these cases in the follow-up out-patient clinic. Secondly, with regard to teaching, all students in their third year attended a weekly two-hour clinic throughout the session of thirty teaching weeks. A systematic course was given covering the fundamentals, architecture of bone, the anatomy of displacements and deformities, and the repair of bone. Regular and irregular type fractures were studied and illustrated by cases from the wards or out-patients. In the out-patient department the students were taught to apply and reapply splints, plaster, and apparatus, also the practical application of the means employed for restoration of function. In the fourth and fifth years the surgical dressers were assigned to the fracture beds in rotation. In other words, the fracture beds were included in the number of beds in general surgery which were utilized for teaching. Professor Bazin did not believe that any student could be induced to follow through from first to last any one patient—for example, with a fracture of the femur. But with their system all of the students throughout three sessions had the opportunity of seeing and studying many cases in all stages of treatment and rehabilitation. So satisfied were they that the method was the right one that they aimed to extend and develop the department as a unit.

Mr. W. R. BRISTOW (London) said that it was evident from the remarks made by the openers of this discussion that it was generally felt that all was not well with regard to the management of fractures, but there was a very clear-cut division of opinion as to what procedures should be adopted by way of remedy. The question of segregation or non segregation was the first point to be considered. There could be no question as to which method was the better for the patient—all were agreed as to the benefit he derived from specialized treatment. This must be, as Mr. Wade had emphasized, of paramount importance. Mr. Bristow agreed that the student would learn best when the treatment was of the highest efficiency. Mr. Gask opposed segregation, and many surgeons agreed with him, because they feared that the teaching of the student would suffer. Mr. Bristow agreed that it was the duty of the teaching hospitals to turn out good doctors. But was the teaching with regard to the handling of fractures good under the present system? He agreed with Sir Robert Jones that it fell a long way below the required standard. But it was not to the surgeons attached to the staff of a hospital but rather to the general practitioner that the question should be put. There was little doubt as to his answer. It was easy even if somewhat cheap, to argue against extreme segregation—to say, for example, Why not have a specialist or special department for diseases of the little finger? But if criticism was to be constructive, why not equally consider a well established specialty like gynaecology—separate wards, separate teachers and now, he believed, in some institutions at any rate, a five or six months' course devoted to this subject? Had the result on the student been deplorable? No. Why, then, should the teaching of fracture treatment in special wards, or in a special part of the out-patient department, be such a hazardous undertaking? It was true that with special departments springing up on one had better say, arising by a natural process of evolution, the medical curriculum, and the way the student spent his time in the wards and out-patient department, needed some revision. It was said that students knew less of tuberculosis, less of venereal diseases, and so on since these branches of the work had been segregated. Mr. Bristow thought this was certainly true, but this did not necessarily mean the segregation in these departments was wrong. In his opinion the student's time should be so parcelled out that attendance in such departments was part of his routine. They were told his time was already fully taken up, but was it taken up to the best advantage? The old system of teaching was the master and his apprentice: they had lost the master, the work had been divided and much of it was treated elsewhere. Neither in his wards nor in his out-patient depart-

ment did any one man collect the varied material the old surgeons used to do. They might deplore the fact, but the fact remained. But what of the apprentice? Mr. X's dressers met him in the central hall and dutifully followed him round his wards and stood by in his theatre. They had little or no time to go elsewhere. If Mr. X did not care for fractures, or worse, if evening, had not the time, or the aptitude, to deal with them, the dressers suffered. Mr. Bristow suggested, with all deference to tradition, that in nine months' surgical dressing time could, and should, be found for definite work in a fracture clinic, even if the dressers were detached from the master for this purpose. Again, the teacher's interest in bone and joint surgery did not narrow his outlook and make him a poor teacher: the personal factor was all-important. It was not a question of brilliance, or special knowledge, or even all round knowledge of other branches of medicine or surgery—some men could teach, some could not. Mr. Gask seemed to think that the specialist was not the best teacher for the student and yet in Gask and Wilson—written, one would imagine, for the student—the section on fractures was written by the orthopaedic surgeon of St. Bartholomew's Hospital. For the average student a more intensive teaching and training in fractures was an urgent need, and Mr. Bristow believed that segregation under men specially trained and interested in the work was the only way this need could be supplied.

SECTION OF DISEASES OF CHILDREN.

ROBERT HUTCHISON, M.D., F.R.C.P., President

DISCUSSION ON THE TREATMENT OF EMPYEMA

OPENING PAPERS

I.—HECTOR C. CAMERON, M.D. CAMB., F.R.C.P.,

Physician in Charge of the Department for Diseases of Children, Guy's Hospital

In opening this discussion upon a disorder the treatment of which is primarily surgical, I must remember that I am to be followed by Mr. Souttar, and that it falls to his lot, and not to mine, to have real opportunity of assessing the value as well as the technical difficulties of different operative procedures. It seems to me right that I should confine myself to a consideration of what may be called the more medical aspects of empyema. To do so does not imply that I am to deal only with matters of secondary importance, for empyema is almost never a primary disease, but in general a complication of some form of pneumonic infection of the lung. The prognosis as to life is, and must be, profoundly influenced by the character of the pneumonia to which it owes its origin.

A discussion on the treatment of acute empyema in children can start with no other consideration than that of the very high mortality in the first two years of life. Almost all statistics show a death rate of about 75 per cent in the first year and of 50 per cent in the second. In the third year there is a sudden drop to about 18 per cent, and thereafter the figure remains constant at a low figure—6 per cent or less. With a death rate varying so greatly from year to year it is not possible to make any statistical survey of cases as they occur in childhood as a whole. A result which would mean a notable advance in treatment in the first year of life would imply failure in the fifth.

The high mortality in the first two years of life is, I think, undoubtedly due to the character of the pneumonia commonly met with at that age. In older children, as in adults, it is always a favourable feature when the rise of temperature due to the pneumonia is separated from that due to the empyema by an interval of time. It is an unfavourable feature if the empyema develops at a time when the pneumonic process is still active and when, upon our chart, the curve of the pyrexia due to the empyema is superimposed upon and blended with the curve of the pyrexia due to the pneumonia. In other words, the empyema which may be described as metapneumonic is of relatively good prognosis, that which is synpneumonic is

of relatively bad prognosis. The high mortality in the first two years of life becomes explicable when we consider that it is precisely in the first two years of life that pneumonia, both of pneumococcal and of streptococcal origin, tends to be of very long duration. Within that age limit it is the exception and not the rule to encounter the short-lived pneumonia of adult type with lobar distribution and termination by crisis. An empyema which develops in the course of a pneumonia which lasts three or four weeks is almost certainly an empyema which must be described as suppurative, that which complicates a pneumonia of five or seven days' duration is likely to be metapneumonic.

In the third year of life we encounter a somewhat sudden change in the type of pneumonia and the short-lived lobar type establishes itself as by far the most frequent variety. In the first two years of life metapneumonic empyema is comparatively rare, suppurative empyema distressingly frequent. The high mortality of empyema in the first two years of life is due to peculiarities of the acute primary pneumonia of infants, which from its longer course and its greater tendency to give rise to simultaneous infection of parts remote from the lung—the meninges, for example, the middle ear, the pericardium or the peritoneum—seldom produces the metapneumonic type of empyema, which we may define as a residual collection of pus localized in the pleura after the termination of the acute pneumonic process in the lung. With the sudden disappearance of the form of pneumonia characteristic of infancy metapneumonic empyema in this sense becomes the rule and the prognosis shows a correspondingly sudden improvement.

There have been many exhaustive studies of the bacteriology of empyema in childhood. It is clear that the pneumococcus, the most common organism to be isolated in childhood, has a prognosis considerably more favourable than the streptococcus, and it is significant that as a rule the empyema due to the streptococcus appears relatively early during the height of the illness and torremia due to the lung infection. It is especially apt to be associated with small scattered abscesses situated in the pulmonary tissue immediately beneath the pleura. Tuberculous empyemata are rare before the fifth year. Staphylococcal empyema, especially in the newly born, is commonly metastatic and may originate in umbilical sepsis, osteomyelitis, or some other infection of a remote part. Such metastatic empyemata are almost always fatal.

The distinction between metapneumonic and suppurative empyema has an all-important bearing upon the question of the treatment to be adopted. Open operation with resection of rib performed upon children with metapneumonic empyema gives highly satisfactory results, no matter what the age of the child may be. The mortality is little greater in the first two years than in the tenth. Death is only to be feared in cases in which there is very great weakness and prostration with extreme emaciation. On the other hand, the open operation with resection of rib, performed in cases of suppurative empyema in the first two years of life, has a very high mortality.

In 1923 Osman and I¹ investigated this point, so far as it is possible, in a series of 52 consecutive cases of empyema in children under 2 years admitted to Guy's Hospital. Of the 52 cases 13 recovered and 39 died. Of the 13 cases which recovered 12 were clearly to be classed as metapneumonic. All of these 12 cases were alike in that they showed no symptoms of pneumonia at the time when the diagnosis of empyema was made. High temperature, rapid pulse, urgent and distressed breathing, cyanosis, delirium, meningismus, expressionless faces, etc., formed no part of the picture. The symptoms of these metapneumonic cases were less striking. The mothers, as a rule, complained of the child's wasting, of an alteration for the worse in appetite, energy, and temper, of pallor, of persistent dry cough, or of intermittent attacks of diarrhoea. When it was recognized that the child had suffered and recovered from an attack of pneumonia, these indefinite symptoms were always dated from that attack and were regarded as an unsatisfactory

convalescence from it. Examination showed a pale, fretful, wasted child, with, as a rule, but a slightly irregular temperature, who became dyspnoeic only after exertion or after crying.

In our series all of the quiescent metapneumonic cases recovered after resection of rib. On the other hand, all the suppurative cases but one died. In the single suppurative case which recovered it appears likely that the termination of the pneumonia and the operation coincided in point of time. Of the 39 fatal cases, 18 were submitted to operation. In the remainder no operation was done, either because the empyema was not located during life or because the child appeared too ill. Of the 18 deaths after operation, 9 occurred within twenty-four hours of the resection of the rib, the remaining 9 at varying intervals thereafter. Of the 39 fatal cases, the *post-mortem* notes were available for examination in 36. In 28 pneumonia more or less extensive was present, in 10 suppurative pericarditis, in 1 peritonitis, in 1 meningitis. In only one case was none of these fatal conditions present—that of a young infant who died a few hours after resection of a rib on the seventh day of an illness marked by very high fever and a very rapid pulse. An acute streptococcal empyema alone was found without pneumonia and without pericarditis.

From a study of these cases Osman and I draw the following conclusions:

1. The high mortality of empyema in the first two years of life is due to the specific character of acute primary pneumonia in infancy.
2. Submitted to the radical operation with resection of rib etc. pneumonic cases almost always recover. suppurative cases almost always die.
3. Metapneumonic empyema should be dealt with by resection of rib as speedily as possible.
4. Suppurative empyema should not be subjected to resection of rib until after the termination of the pneumonic process. Some form of paracentesis should be practised as a temporary measure.
5. In suppurative cases death occurs from the original pneumonia and from metastasis of infection to other parts rather than from the empyema.

Circumstances have not enabled me to test the truth of these conclusions upon any considerable scale. I am unable to disprove the objection which may be very reasonably raised, that the cases which recovered did so because they suffered from a relatively mild infection or were possessed of a relatively high resistance, and that in the cases which died death would have followed equally soon and with equal certainty had they been treated by repeated aspiration in the hope that later, after recovery from the pneumonia, the radical operation might be performed in more favourable circumstances. The vast epidemics of influenza occurring during the war in training camps and elsewhere provided ample material for an investigation of this character. It is true that the material available was adult material but, on the other hand, the type of pneumonia which occurs during influenza, both in its symptoms and in its *post-mortem* appearances, presents a much closer resemblance to the lobular pneumonia of very young children than to the lobar pneumonia of adult type.

Thus the findings of the Empyema Commission of the United States seem to me of great importance as bearing directly upon this point. When the commission substituted a method of repeated aspirations until after recovery from the pneumonia for the method of immediate resection of rib previously employed, the mortality fell from 40 to 4.3 per cent. At Camp Lee the following was the experience:

- First Series.* Early operation. October, 1917 to January, 1918, 85 cases mortality 61.2 per cent.
Second Series. Early aspiration late operation, January 1918 to August 1918. 96 cases mortality 15.6 per cent.
Third Series. The same. October 1918 to February, 1919, 94 cases mortality 9.5 per cent.

These figures certainly support the conclusion derived from the study of the results obtained in young children at Guy's Hospital—that the performance of the open operation at too early a stage is dangerous and adds greatly to the mortality.

But successful treatment must be concerned not only with the saving of life. It must consider also the complete restitution of the function of the lung. Chronic empyema, which implies a failure to achieve complete obliteration of the cavity, is much more rarely met with in childhood

thru in adult life. The resilience of the thorax and the high degree of elasticity of the lungs, are no doubt factors acting favourably. We may in almost all cases regard the failure as due to the excessive formation of fibrous tissue around the cavity, so that there forms a space with thick and rigid walls which will neither collapse nor yield to the force which the lung exercises in its attempt to expand. Different factors contributing to this result may perhaps be set out as follows:

1 A too great delay in the establishment of satisfactory drainage

2 Insufficient drainage or drainage unsuitably placed

3 Secondary infection of the cavity from accidental contamination from without or from the presence of a bronchial or pulmonary fistula or of a foreign body such as a piece of rubber drainage tube which has slipped inwards

Let me briefly consider these points in turn

1 That in the case of young children and in certain influenzal cases it may be wiser to withhold operation until after the termination of the pneumonia does not contradict the general rule that any delay in operating makes it increasingly likely that the formation of fibrous tissue in the pleura will prevent or make difficult the proper expansion of the lung. The two considerations pull us in opposite directions. In a child struggling with pneumonia the sudden formation of an open pneumothorax with great mediastinal displacement, may turn the scale against recovery. Moreover, at an early stage the pleural infection takes the form of a diffuse cellulitis. Later adhesions both stabilize the mediastinum and localize the infection. But delay still carries with it its own dangers. In infancy we are most concerned with saving life, after the third year the risk to life is slight and the complete recovery of the function of the lung is our main consideration. It remains true of most of our bad results that the difficulties grow out of a failure to make an early diagnosis of empyema, and that the fibrosis of the walls was far advanced before operation.

2 Drainage must be adequate and the opening suitably placed. Without some fairly accurate knowledge of the exact shape and capacity of the cavity there must always be a risk that the drainage tube may be removed too soon, while the sinus contracts and affords inadequate drainage to a cavity only in part obliterated. Probing, irrigation with measured quantities of fluid, illumination by an instrument devised on the principle of a cystoscope, and radiography may all assist in investigating the shape and extent of the cavity.

3 It is probable that secondary infection is not uncommon. Moist antiseptic dressings offer obvious advantages over dry sterile pads, both in preventing accidental contamination of the wound or of the discharges and in excluding the air from the pneumothorax. A fistulous communication with a bronchus is the usual termination if an empyema is left undrained. This spontaneous escape of pus is seldom rapidly achieved. It is rare to find expectoration of pus from an empyema cavity before the eighth week, and the interval is usually much longer.

The date of the opening of the fistulous communication may sometimes be determined by the circumstances that while bronchial secretion is tasteless, the pus from the empyema has a peculiar bitter taste. After irrigation with Dakin's solution the taste of chlorure may be noted in the mouth. Surgical methods have been successfully devised by which a wedge-shaped piece of the lung containing the fistulous opening may be excised, yet it is probably true that the main difficulty in these cases is concerned not so much with the fistulous track as with the rigidity of the dense fibrous tissue which has grown around the empyema cavity in the long interval before the pus at length found an exit.

Irrigation is of service in disinfecting the cavity and in preventing the formation of adhesions with localization of the pus. With a sufficiently free outlet and with unobstructing solutions it is without ill effect. Accidents formerly described appear to have been due to the use of strong antiseptic solutions or to too great pressure. Dakin's solution appears especially of value because it possesses quite remarkable powers of softening and disintegrating newly formed fibrous tissue and organized lymph. The

discharge of large fibrous casts from the surface of the lung, after its continuous use, has often been noted.

If all of these sources of failure are avoided recovery should be rapid and complete, because the lung, in the absence of a rigid, uncollapsible, and indistensible fibrous covering, is free to expand and obliterate the cavity from which the discharge originates.

Many attempts have been made to assist the lung to expand and to force asunder the adhesions which bind it down. The methods of "siphon drainage" and "negative pressure drainage" are complicated and require constant supervision if free drainage is not to be impeded. In a sense they may be said to attack the problem from a wrong quarter. The primary aim must be to avoid the formation of fibrous tissue. If the lung is bound down by a rigid covering of fibrous tissue, decortication is indicated. If the lung is in a condition to expand, all devices to increase the negative pressure are unnecessary, if it is not in a condition to expand they are ineffective.

Of resection, followed by immediate closure of the wound, I have no experience. If it is to be successful it would seem that its use must be confined to cases in which immediate expansion of the lung is possible, which give the best results with the more usual methods.

II—HENRY S. SOUTTAR, C.B.E., M.Ch. Oxon.,
F.R.C.S.,

Surgeon (with care of Out-patients), London Hospital

THE TREATMENT OF ACUTE EMPYEMA IN CHILDREN

Incidence and Mortality

It will be generally acknowledged that acute empyema of the pleura is a fairly common disease in childhood, and that its importance on this account is enhanced by its high mortality in early years. Yet to obtain accurate statistics on the subject is very difficult, and those which are available are marred by a disappointing divergence. Thus at the London Hospital, where we deal with most diseases on a generous scale, our annual cases of empyema have in the last fifteen years varied between 46 and 112, and our mortality between 85 and 40 per cent, without any obvious reason. Empyema is, indeed, only one local detail in the clinical picture, and it may be entirely overshadowed by general features of decisive importance.

From a study of certain large groups of cases a few statistical facts of real interest do, however, emerge. In the fifteen years from 1909 to 1923 there were treated in the London Hospital 1,310 cases of empyema, excluding those which arose secondarily to surgical conditions. Of these, 655, or exactly half, occurred below the age of 10. This agrees fairly well with the 425 cases from Johns Hopkins Hospital quoted by Heuer, 182 of which were below the same age. Even in this restricted period the incidence is uneven, for no less than 70 per cent of the cases in the first decade occur in the five years between the ages of 1 and 6, so that when we speak of the treatment of empyema in children it is this period which we must chiefly bear in mind.

The mortality of empyema in early years is even more striking than the incidence of the disease. In 1923 there were in England and Wales 445 deaths from empyema, and of these 143 were in the first decade. But of these last cases no fewer than 119 occurred in the first five years of life, and 97 of these were between the ages of 1 and 4. It is in these years that empyema is most fatal. It is true that in the first year the mortality is highest of all, reaching 75 per cent, but the number of cases is small. In the second, third, and fourth years the disease is common and the mortality anything from 40 to 60 per cent. Holt reports 204 cases in the first two years—14 in the first year with 10 deaths (74 per cent), 190 in the second year with 112 deaths (59 per cent), or a general mortality for the first two years of 60 per cent. Cameron and Osmani report 52 cases from Guy's Hospital in the first two years, with 39 deaths (75 per cent). Brown, from the Children's Hospital, Philadelphia, reports 149 cases between the ages of 1 and 4, with 51 deaths, and a mortality averaging 34 per cent over this period. The London Hospital statistics are shown in detail in the adjoining tables.

TABLE I—Cases of Acute Empyema in the London Hospital 1909-23 inclusive

Age	Male	Female	Total	Deaths	Mortality
0-10	397	258	655	189	28
10-20	125	54	179	11	6.1
20-30	113	61	174	27	15.5
30-40	82	35	117	23	19.6
40-50	74	29	103	32	31
5-60	52	14	66	26	39.4
6-70	11	2	13	5	38.1
70-80	0	3	3	0	0

9-10	19	6	25	0	0
Total	397	258	655	189	28

CHART B—Cases of acute empyema in the London Hospital under the age of 10 in the years 1909-23 inclusive. Age incidence and mortality

The heavy mortality in the first two years, and the sharp drop which occurs after the age of 5, are especially to be noted.

There is another curious fact in the incidence of empyema, that, taking all ages, the males outnumber the females by about 2 to 1. In the ten years ending with 1923 there was an annual average of 314 male deaths and 151 female in England and Wales. In later years increased exposure may play some part in the divergence, but even before the age of 10 the difference is marked, there being in the year 1923 88 male and 55 female deaths. This is in curious close agreement with the London Hospital statistics, for in fifteen years we had 401 male and 260 female cases of empyema under 10. Sex, however, appears to affect the incidence only and not the mortality of the disease. In our own figures 110 males and 81 females died—mortalities respectively of 27 and 31 per cent.

Etiology and Pathology

The mode of onset of the disease has a vital bearing on the mortality and on the method of treatment. When the empyema occurs as one feature of a general infection, as in pneumococcal septicæmia, or where the whole cavity is suddenly involved in a virulent infection, probably streptococcal the outlook is bad, and any attempt at immediate radical treatment will lead to disaster. When, however, the pleural cavity is infected by extension from a subsiding pneumonia the outlook is much more hopeful, and radical treatment is indicated, both to cut short the disease and to avoid such complications as pulmonary fibrosis, bronchiectasis, and bronchial fistulae.

In children at least empyema is very commonly associated with an underlying pulmonary condition. Fraser found that in 25 per cent of his cases there was a true lobar pneumonia, and in 50 per cent a bronchopneumonia, whilst in the remainder there was a general influenzal infection. Cameron and Osman have pointed out the difference in outlook in those cases which are consecutive with and those which are consecutive to the pulmonary condition. Under the age of 2 the synpneumonic cases are almost invariably fatal, whilst of 12 metapneumonic cases every one recovered.

Equally important is the nature of the organism producing the infection. Fraser found that of 70 cases in children, 53 showed a pure pneumococcal infection and 17 a streptococcal. In the former the mortality was 6 per cent, in the latter 24 per cent. This agrees with Binney's figures, for in 89 cases at all ages he found that 73 were due to the pneumococcus, 16 to streptococcal and staphylococcal infections, whilst the mortality in the latter was twice that of the former.

These facts find their explanation in the general and the local reaction of the individual to infection. Where the child is overwhelmed by a virulent infection to which it can offer no adequate resistance, an empyema is simply an incident—of grave import, it is true, but not the really critical factor in the situation. Mortality will inevitably be high, and surgical interference must be limited to the relief of mechanical conditions. When the infection is less virulent and the resistance better, there will be time for the formation of adhesions which limit the extent of the pleural infection and very materially affect the treatment of the case.

The formation of pleural adhesions is indeed a factor of the greatest importance from the surgical standpoint, and in this there is a marked contrast between pneumococcal and streptococcal infections. In the former massive adhesions are formed, limiting to some degree the extent of the empyema, binding the visceral and parietal layers of the pleura together, preventing gross collapse of the lung, and protecting the mediastinum from pressure. It is true that these adhesions may ultimately limit the expansion of the lung, delay recovery, and lead to the formation of a chronic empyema. But for the moment they are of undoubted advantage.

In contrast to this a streptococcal empyema usually involves the whole cavity, the lung is grossly compressed and lies squeezed up against the spine, whilst the mediastinum is driven across to the opposite side, and there is severe mechanical interference with the circulation in the heart.

and the great vessels. As Fraser points out, the two conditions produce very different effects upon the respiratory oscillations in intrathoracic pressure, the nature of which is shown clearly in the accompanying diagrams. In the

CHART C—Oscillations of intrathoracic pressure in a child 5 years of age

normal child the intrathoracic pressure is negative in every phase, in a pneumococcal empyema with adhesions it is positive in every phase, whilst in a streptococcal case without adhesions there is negative pressure on inspiration and a positive on expiration. So characteristic, indeed, are these pictures that it is possible from them alone to predict the findings of the bacteriologist.

There is one other very striking feature in any large group of empyemata—the influence of complications upon the mortality. Heuer states that in the Johns Hopkins series of 425 cases the mortality in the presence of complications was about 50 per cent, but when these were absent it was only 6.5 per cent. In children the contrast is even more striking, for in every case under 10 where an autopsy was obtained some grave complication was present. In the 52 cases under 2 years old reported from Guy's Hospital by Cameron and Osman the same facts appear, for death was probably invariably due to a complication—such as pneumonia in the acute stage, suppurative pericarditis, peritonitis, or meningitis—and never to an uncomplicated empyema.

The bearing of these considerations upon treatment is very direct. Where acute pneumonia is still present, where the empyema is one symptom of a general streptococcal infection, and where any grave complication is present, the surgeon will do well to remember that the empyema is only one factor in the case, and to exercise his judgement in assigning to it its proper position. The question of adhesions or their absence introduces, as we shall see, a factor of vital importance into the consideration of the surgical problem.

Operative Treatment

As regards operative treatment, empyemata fall into two groups—the adherent and the non-adherent. We have seen that the former are usually pneumococcal, and frequently they show pneumococci in pure culture. They are often loculated, they contain thick greenish pus which can only with difficulty be drawn through an aspirating needle, the pleural surfaces are covered with thick layers of plastic lymph, and floating in the cavity itself are large masses of soft fibrin. The non-adherent form is necessarily complete, it is usually due to streptococci or to a mixed infection, the pleural cavity is full of thin pus, gas-forming organisms are often present, and the condition is generally one of pyo-pneumothorax. In this form the intrathoracic pressure may be very high, the intercostal spaces bulge, the mediastinum is pushed over to an excessive degree, and the diaphragm and liver are pushed downwards. Obviously the two forms involve surgical considerations of a very different nature and demand very different methods of treatment.

In the first or adherent form there can, in our opinion, be no doubt that the best method of treatment is to open the cavity freely, evacuate the pus, clear out all solid masses of fibrin, and drain by a closed method. As there are sufficient adhesions to prevent the sudden collapse of the lung and the formation of a complete pneumothorax, there can be no objection to a free opening which gives adequate access to the interior of the chest. Without thus the removal of large solid masses is impossible and to

leave them behind is to leave an ideal culture medium for bacteria, greatly to delay the sterilization of the cavity, and to facilitate the formation of such massive adhesions as may ultimately postpone indefinitely expansion and recovery of function in the lung.

In a young child with a soft thorax an intercostal incision will give sufficient access, but in older children the resection of a rib is more satisfactory. In view of the possibility of loculation by adhesions it is essential that the incision should be over the precise point from which pus has been obtained, generally in the region of the eighth or ninth rib in the posterior axillary line. Either four inches of rib should be resected or a longer intercostal incision made. The pleura is exposed, and if it is thickened and its separation is easy it is well to separate it from the chest wall for an inch around the incision to facilitate subsequent closure. A small incision is now made in the pleura, and quite slowly the pus is allowed to pour out. We are convinced that caution at this stage will be amply repaid and that rapid evacuation of pus under pressure is thoroughly bad surgery. After a few minutes, when the pus is no longer under pressure, the pleura may be freely opened and a finger inserted to clear out solid masses. With a gauze swab in a holder they may be very gently detached from the pleura, the greatest care being taken to avoid bleeding, or irritation of the pleural surfaces. An occasional cough will help to empty the cavity and expand the lung, but a violent fit of coughing will gravely affect the mediastinum and should be avoided by extreme gentleness in all manipulations. A large tube is now inserted at the lowest point of the thoracic cavity, either through a fresh incision or through the primary opening. In either event the thorax is most carefully closed except for the tube, around which the tissues should fit quite airtight. The pleura itself and the deep fascial layers should receive especial attention. Finally, a large tight-fitting coil or a perforated sheet of rubber is threaded over the tube and incorporated in the dressings so as to hold the tube in place. The tube itself projects through the dressing and is connected to a long rubber tube the end of which hangs below fluid in a jar on the floor beside the patient's bed.

The great advantage of this method is that it allows full exposure and free drainage without the risks of secondary infection, which are inseparable from the ordinary method of open dressing. The dependent tube produces a constant slight suction on the pleural cavity and encourages early expansion of the lung.

In the non-adherent form of empyema, on the other hand, to open the pleural cavity freely and at once is to court disaster. The safer plan is to relieve the pressure by repeated aspiration, perhaps daily for five or six days. In this way the lung and heart are relieved to some extent from the mechanical pressure of the effusion, toxic absorption is diminished, and an opportunity is given for the formation of adhesions, which will prevent total collapse of the lung when the thorax is finally opened for drainage, and which will to some extent limit the infective process.

At the end of this time the actual procedure to be undertaken will depend upon the circumstances of the case. If the child is still dangerously ill and shows the signs of a marked toxæmia, or if there are signs of involvement of the opposite lung, interference must be reduced to a minimum. In such a case a small intercostal incision, with the insertion of a closely fitting tube and aspiration drainage as above described, is all that should be attempted, and every effort must be made to prevent the formation of an open pneumothorax. In children under 3 this is always the method of choice.

Where the child's condition warrants it, there are, however, advantages in a more complete exploration. The pleural cavity is opened as described above in the pneumococcal cases where adhesions are present, the greatest care being taken not to break down any adhesions. Solid masses of fibrin and debris are gently removed, and closed siphon drainage is established. In some cases, and especially where the pus is foul from the presence of gas-forming organisms, the cavity may be very gently washed out with saline, but in this case a suction apparatus should be used to extract the fluid as rapidly as it is supplied.

rehabilitation of non-resection methods under modern conditions. Resection was, and is, employed in young children almost as a routine, and this, to my mind, is utterly wrong. I have seen cases end disastrously that I believe might have been saved if less drastic measures had been pursued, such as preliminary aspiration, or treatment by simple incision and drainage. In children under the age of 4 treatment by primary resection is, I think one can say without exaggeration, unjustifiable. In the *St Bartholomew's Hospital Reports of 1924*, in a review of the treatment of acute empyema, I give figures of a number of cases so treated, and the consideration of the mortality showed it to be appallingly high, this has been brought out strikingly in the excellent contributions of Dr Cameron and Mr Souttar. Nevertheless, this high mortality until recently has not been sufficiently recognized.

Treatment of Ordinary Empyema

In treating the ordinary empyema we have four things to keep in mind: (1) the evacuation of the pus, (2) the expansion of the lung, (3) the speediest convalescence, (4) the comfort of the patient, and our measures must be directed towards these ends. As a rule there is little difficulty in evacuating the pus, it is the expansion of the lung that causes the trouble in the great number of cases that do not go well. For this reason suction drainage has been employed. In the article already quoted I endeavoured to show that, apart from a number of mechanical difficulties associated with this procedure, it is tackling the problem from a wrong aspect. If the lung does not expand it is because there is disease within it, or because it is held prisoner by thickened pleura or adhesions at least these are the natural reasons. It may be prevented from expanding by the insertion of a huge foreign body masquerading as an enormous drainage tube, a relic of an old-time superstition that still survives in some places.

If there is intrinsic lung disease ordinary incision and drainage by a small tube will suffice until the lung has recovered when it will expand. If a thick pleura or adhesions are the trouble these can be dealt with mechanically or by irrigation with Dakin's all-rhine solution. For this a wider opening would be necessary which would probably have to be made at a second operation when a resection might have to be done, but by this time the child would be less desperately ill and could support it.

Treatment of Acute Fulminating Empyema

A different problem confronts us when dealing with what I have called the acute fulminating empyema. By this type I mean that sort of case where the patient is taken ill and shows all the signs of a huge pleural effusion within twenty-four or forty-eight hours, and where exploratory puncture reveals pus, usually the reddish-brown pus due to a streptococcal infection. To my mind there is for this condition one treatment, and one only, and that is gentle aspiration repeated several times if necessary until the patient is sufficiently well to support severe measures. Then an incision can be made usually under a local anæsthetic, and lastly, if necessary, when the patient's general condition is good, a resection can be performed if decortication or frequent pleural lavage is indicated. There is one warning that must be given in aspirating this sort of empyema, or in fact any pleural effusion, and that is the danger of producing too high a negative pressure in the pleural cavity; it can easily happen and its results may appear with startling suddenness. For instance, I was called out to see a boy who had had an influenzal attack, and who in the space of two or three days had developed a very large pleural effusion and was desperately ill. Exploration revealed reddish brown pus. I aspirated this very gently by means of a bottle in which a negative pressure was maintained by means of a Higginson's syringe. After about a pint of pus had been withdrawn the patient suddenly cried out in acute distress and became intensely cyanosed. I at once slipped the tube from the aspirating needle, placed some cotton-wool over it, and told the child to breathe deeply, which he did. Air was sucked very audibly into the pleural cavity and the symptoms were at once relieved. I then aspirated altogether two pints, allowing air to enter the

chest in the manner described whenever the patient told me he began to feel uncomfortable. This, therefore, was a simple and crude, but effective, method of an replacement, and so to my original statement that the treatment of the acute fulminating empyema is aspiration I must add that in certain cases it must be aspiration and replacement by air or oxygen.

IV—W. H. C. ROMANIS, M.C., F.R.C.S.,
Lecturer in Practical Surgery and Assistant Surgeon to
St Thomas's Hospital, Surgeon, City of London
Chest Hospital

Most speakers have laid stress on the mortality of empyema in children under 3, and with this I am cordially in agreement. But I do not think that sufficient attention has been drawn to the fact that in those patients who recover there is still a grave liability to such serious chronic troubles as sinus, fibrosis of lung, and bronchiectasis, and it is our duty, when called upon to treat a child with an empyema, as far as possible to consider the possibility of these after-effects as well as the immediate problem of saving the child's life. Empyema in children may be regarded from the point of view of surgical treatment as of four main kinds: those due to the pneumococcus, those due to the streptococcus and other organisms, those which are early, and those which are late, it is of the greatest importance to ascertain the nature of the organism before any operation is performed. In the pneumococcal cases, and especially the late pneumococcal cases, there is always the possibility—nay, probability—that large solid masses of fibrin and also pleural adhesions will be present, while in those cases due to streptococci and other organisms this is far less likely, though the toxicity and virulence of the infection is usually far greater and the prognosis worse. It must be remembered that these huge masses of fibrin in the pleura will often mask the physical signs and conduct the breath sounds to the surface of the chest in a remarkable way. When dealing with an empyema in an adult one of the most important considerations before the surgeon should be a thorough exploration of the pleural cavity with a view to the removal of solid masses of fibrin or slough, as these may materially interfere with the healing of the wound and the expansion of the lung, while in the adult, in most instances, the operation will be followed by open drainage of the pleura, achieved by the resection of a rib. But in children this is not so, for though the removal of solid fibrous masses is still important, everything must be done to diminish the shock and magnitude of the operation, while there is no doubt that small children do not tolerate open drainage of the pleura at all well. In an early pneumococcal case in a child, therefore, when the pus has been present less than four days, I think that repeated aspiration should be tried for a few days, and in some cases it may be that this will suffice to cure the condition. If, however, it is followed by no relief, or in those instances where the pus has been present for more than six days, the pleura will have to be opened and—provided that the patient seems fit to stand it—gently explored, and masses of fibrin removed, great care must be taken not to break down adhesions. This can easily be done without resecting a rib if a small rib-spreader is used, for children under 3 I prefer not to resect a rib. In patients over that age a rib may be resected, as it will give easier drainage. The operation must be followed by drainage, but this should not be the ordinary form of open drainage appropriate to the adult pleura, it is best done either by means of a suction apparatus such as that already described by Mr Souttar—though this may be troublesome in a tiny child who is restless—or perhaps better by a tube which is stitched in so as to be as nearly watertight as possible, and the end of which is closed by a stopper or clamp. The nurse then removes this stopper and allows the tube to drain for a few minutes every four or five hours. In those cases in which no rib has been resected the tube should be of metal, and rather resemble a large tracheotomy tube. I do not think that primary suture of the wound without drainage, which is sometimes successful in adults, is ever wise in children. Before passing to consider those empyemas which are due to other organisms, I wish to emphasize the fact that in

most cases of pneumococcal empyema there is no great urgency about performing an operation, and usually a delay of a day or two (during which aspiration may be performed) will do good and not harm.

When dealing with empyema due to streptococci or other septic organisms the problem is rather different. It is the need for exploration of the pleural cavity is less, but the urgency of drainage is far greater, though a preliminary aspiration may sometimes be performed, this should not be repeated, as it will do no good. Here drainage is urgently required, and again it should not be open drainage, but should be achieved by one or other of the methods already described. Again in children under 3, I prefer not to resect a rib. In those patients who are desperately ill, and in whom even this procedure of incision and drainage might be too severe, improvement can often be obtained by inserting a large trocar and cannula between the ribs and connecting a tube to the cannula, this is very likely, however, to be followed by infection of the chest wall.

It is in children that the three rare special varieties of empyema—the apical, interlobar, and bilateral forms—are most commonly seen. The chief interest and importance of the apical form lies in its diagnosis—its treatment is not different from that of the other forms of empyema except that its localization must be remembered and the greatest care taken not to disturb or infect the intact pleural space.

The interlobar form is also difficult to diagnose, and with regard to its treatment we must remember that here we are dealing with what is practically a localized abscess in the lung, that there is no question of exploring the pleural space, in fact, this latter structure must be studiously avoided. One of the difficulties in these cases will be to find the pus if it is a small collection, the operation should therefore always be commenced by inserting a needle into the collection of pus, and this is left *in situ* while the chest is opened. There is no need to employ one of the closed methods of drainage when dealing with a localized collection of this kind, and an ordinary open drainage tube may be used.

In the case of a bilateral empyema aspiration must be tried first, on both sides if necessary. If this procedure gives no relief, that empyema which appears to be the biggest should be drained, while aspiration is continued at intervals on the other side. Finally, after an interval of some days, a simple drainage may be performed on the second side.

With regard to the question of the anaesthetic and the position in empyema operations in children, though a local anaesthetic is feasible, I personally much prefer to use gas and oxygen or light ether anaesthesia. With regard to the position of the patient, it is always interesting to hear it insisted upon that the patient must never be laid upon his sound side, for I must confess that I always turn him upon his sound side to do the operation, and neither I nor Dr Shelley, who always anaesthetizes these cases for me, has ever seen any harm come of it.

V—T TWISTINGTON HIGGINS, M.B., F.R.C.S.,
Surgeon to the Hospital for Sick Children,
Great Ormond Street

I am afraid I have no particular panacea to put forward for the surgical treatment of this disease. From the purely operative point of view we have to deal with an abscess, and on general surgical principles we must provide for prompt evacuation of the pus and for such after-care as will ensure the satisfactory obliteration of the abscess cavity. In the case of a pleural empyema we have to rely almost entirely upon re-expansion of the lung for the closure of the cavity, and success or failure, so far as the local abscess is concerned, will depend upon this factor. In addition, however, we have to recognize that the abscess in the pleural sac has vital intrathoracic relationships, from both a mechanical and pathological point of view. These relationships are such as to necessitate careful consideration in each individual case before any decision is arrived at on the question of treatment. It seems to me that the successful surgical treatment depends upon (1) early and accurate diagnosis, and (2) efficient operative and post-

operative treatment, always provided that the child can withstand the infection.

It is obvious that the sooner the presence of pus can be recognized the better, and the precise significance of this finding in the clinical picture must be appreciated so that the empyema may be viewed in its proper perspective—whether symptomatic, metapneumonic, or septicemic. All this is generally regarded as the physician's problem. It is assumed that the surgeon disdains the stethoscope as much as the physician despises the carpenter! I do feel that more intimate collaboration in these cases should be the rule. There can be few diseases in which it is more clearly called for, both before and after operation.

When we come to consider what can be done in any given case, we have at our disposal the following methods of attack: (1) Thoracotomy, with resection of rib, or by simple intercostal incision, followed by (a) primary closure, (b) closed or suction drainage, (c) open drainage. (2) Aspiration either continuous or intermediate. (3) A combination of these methods.

In considering which method shall be adopted the following factors must be weighed in each case: the age and condition of the child, the characters of the pus, the size and nature of the empyema, the site of the empyema.

Age and Condition of Child—Empyema are notoriously fatal in infancy, during the first two years of life for obvious reasons. It has been already pointed out that the fatalities are due to complications, local extension to the other intrathoracic viscera, or general spread to the meninges and so on. The relative violence of the bacterial onslaught in the very young renders these complications frequent at this tender age, and is such that one can hardly hope that any treatment of the empyema will lower the mortality appreciably. Yet there can be no doubt that the additional shock of a severe operation is to be avoided if possible. It is in this group of cases particularly that the method of continuous suction drainage, as described by Poynton and Reynolds, is valuable. Even if the chest has to be opened later the acute crisis may have been safely negotiated. The same applies, of course, to the case of the child of any age whose general condition is grave with an associated active pneumonitis, or in the septicemic cases.

The Characters of the Pus—Thin watery pus invites aspiration. Where the pus is thick—there will almost certainly be many solid "clots"—aspiration will fail. With regard to the bacteriology of the pus, it has not been our experience at Great Ormond Street that this helps us as much as appears to be the case elsewhere. We have not found it possible to say that all the pneumococcal cases should be opened or that the streptococcal cases should be aspirated. I understand that some indications of the patient's resistance can be obtained from noting the characters of the white cells and the extent of phagocytosis exhibited by them. My colleague Dr Hugh Thursfield tells me that he is endeavouring in this way to sort out those cases in which the chest wall might be closed after evacuation and cleansing of the cavity.

Size of the Empyema—Where the empyema is of such an extent as to produce serious respiratory embarrassment and cardiac displacement, of course a preliminary aspiration is clearly indicated—either continuously or as an intermittent procedure at least twelve hours before thoracotomy.

Site of the Empyema—An encapsulated or interlobar empyema is unsuitable for aspiration and must be sought for through the chest wall, by following the track of the exploring needle which has located the pus.

Operative Procedures

Thoracotomy—I am convinced that for the majority of empyema in children this will continue to be the operation of choice or necessity. The important details of this procedure, which have been already mentioned, were impressed upon me many years ago at Great Ormond Street by my senior colleague, Mr G. E. Wagh, and I have had abundant opportunity of proving their value.

(a) *Position of the Patient*—Obviously the good lung must have the fullest possible play, and I prefer the child lying on the face with just a flat soft pillow under the chest so as to simplify the administration of the anaesthetic.

(b) *Anaesthetic*—I am bound to say that I prefer warmed ether and oxygen. I have always hated using local anaesthesia alone in these cases.

(c) *Opening the Chest*—I have scarcely ever used the intercostal incision alone and prefer rib excision.

It is essential to remove a sufficient length of rib so that really good access is given to the cavity. The site chosen is as nearly as possible the most dependent point of the cavity, usually the eighth or ninth rib in the posterior axillary line. Not less than three inches of bone should be removed in a child of 5 years. It is generally possible, and always desirable, to separate the pleura a little, as Mr Souttar mentioned, so as to simplify the subsequent suturing.

Evacuation of the Pus and Cleansing of the Cavity—The pus should, of course, be evacuated slowly and gently. Then a wider pleural opening is made, the cavity thoroughly cleansed of all solid fibrous masses, and the lining walls gently sponged with gauze swabs. In the majority of cases the lung will be seen to come up definitely to meet the chest wall.

Drainage—I am quite satisfied that some form of closed drainage is the best. It simplifies the after-care, leaves the patient infinitely more comfortable, and, I think, definitely shortens the convalescence. The tube is introduced just within the cavity. The layers of the chest wall are sutured accurately round the tube, and this is led away from the bed to some form of suction apparatus. Nevertheless, open drainage is quite successful in many cases. If open drainage be adopted, the tube (large) should only just enter the cavity, and the utmost care is required to prevent secondary infection. We must admit that many cases can be treated quite satisfactorily by open drainage. With regard to complete closure of the chest wall without drainage, I have never done or seen this done successfully in the empyemata of children, and I cannot think that it is ever likely to prove very useful in practice.

Aspiration by means of the Potin apparatus may be valuable as a temporary measure in certain cases, as has been already indicated, for continuous aspiration some form of trocar and cannula, combined with continuous suction, is required. In the method described by Poynton and Reynolds such a special trocar and cannula is introduced under a local anaesthetic into the abscess cavity. The trocar is withdrawn and the rubber tubing, of suitable size and strength, is passed by means of a special introducer through the cannula. On the withdrawal of the introducer the tubing expands so as to fit the cannula tightly. The tubing is connected up to a continuous water-drip suction pump, so that continuous aspiration of the pus into a receiving flask takes place. In successful cases the discharge in a few days becomes scanty and serous, and the an entry and chest excursion indicate satisfactory re-expansion of the lung. The apparatus is a little complicated and requires careful supervision to maintain its efficient working, but the comfort of the child is striking. This method has had a fairly extensive trial at Great Ormond Street, and the results have been distinctly encouraging. It may be definitely said to have been proved of value in selected cases, in which the use of such a method has been indicated.

Lastly, the after-care of these cases is most important, especially breathing exercises to promote re-expansion of the lung on the affected side, after the first two or three acute days are over. The child is encouraged to breathe deeply or to blow out Woulfe's bottles while lying on the side of the healthy lung, or with the chest wall on the healthy side compressed by the nurse's hand, or even strapped.

GENERAL DISCUSSION

Dr CLARKE said he would like to advocate and give his experience of primary closure in suitable cases where empyema of some standing. The advantages were avoidance of secondary infection and the production of a negative pressure in the chest, at any rate temporarily. The operation consisted of making a careful toilet of the pleura and then sewing up tight. Out of some twenty patients three had healed, and none of the others died or had chronic empyema.

Dr L. A. PARRY (Brighton) remarked that there was happy agreement between all speakers on the general

principles of treatment, the variation being only in detail. He agreed with Mr Souttar that irrigation was inadvisable. There was no necessity for it, and it was certainly accompanied by distinct risk. Primary suture held out so small a prospect of success that it was hardly worth attempting. He thought that a piece of rib should be excised in all cases, even in young children, but he did not agree that it was necessary to remove the large lengths suggested—one or one and a half inches was quite sufficient. Breathing exercises to expand the lung were advisable after the operation. In young children bubble-blowing was a simple and efficacious method of performing these exercises.

Mr R. A. RAMSAY (London) thought that the objection to rib resection in very young children was that it made the operation longer and more severe. He was coming more and more to the conclusion that in infants all operative measures should be reduced to the shortest possible time. One of the objections to simple incision was that a large enough tube could not be inserted. This difficulty might be overcome to a large extent by introducing two moderate-sized tubes, after twenty-four hours it was usual to find that a full-sized tube could be substituted. The tube should only just reach the pleural cavity and not project inside it. He was now operating in most of the cases in very young children under local anaesthesia. One point regarding free drainage seemed to him of great importance. While it was undoubtedly true that the ultimate obliteration of the abscess cavity was brought about by the expansion of the lung, there was an immediate diminution of the cavity produced by the collapse of the chest wall and the rise of the diaphragm. This brought these two structures into apposition in their lower parts, and if the drainage tube was placed low, as most speakers had suggested, it came to lie in this practically non-existent cavity with the diaphragm laid against and blocking its opening. For this reason he made a practice of draining an empyema, not at its lowest but at its highest point, by preference at the level of the fifth or even of the fourth rib. Of course the actual site of incision depended on the situation of the empyema and of its upper level. He agreed that when a rib was resected one to one and a half inches was a sufficient length to remove, since a less severe and less prolonged operation was necessary than when three inches were removed. The smaller length gave an opening large enough to admit a drainage tube, and especially for the finger to be introduced.

Dr J. WILKIE SCOTT (Nottingham) pointed out the difficulty of obtaining pus by exploration of very chronic empyemata when the condition was obscured by the presence of a great degree of fibrosis, and the difficulty of draining such cases. Sometimes only a few drops of pus could be obtained, and he raised the question as to whether in such cases it was not best to aspirate, or, if a piece of rib had been resected, to close the chest completely afterwards.

Mr P. T. CRYMBALE (Belfast) agreed with Mr Ramsay that the apical part of an empyema was the most difficult to drain satisfactorily, the lower part was closed by elevation of the diaphragm. In a large empyema the fourth rib should be selected for resection. There was difficulty in exploring an empyema cavity if the incision was too small. In his experience treatment of chronic empyema was most unsatisfactory, the cases relapsed constantly. Decortication was a dangerous operation, and not to be undertaken if it could possibly be avoided.

Dr C. F. COOMBS (Bristol) was interested to find an increased sense of the gravity of operations on the thorax. He found himself increasingly impressed by the need for seeking the most skilled surgical assistance available, and for close co-operation between surgeon and physician in the treatment of empyema.

Dr CAMERON, in reply, said that one point came fairly out of the discussion, namely, that in the details of surgical procedure—the site, the extent of the incision, the character of the drainage, and so forth—there was very great divergence of opinion. It seemed to him that the

prognosis was mainly determined by one consideration only whether or not intervention was made at the right moment. He thought the same was true in pneumococcal peritonitis. The evacuation of a residual collection of pus gave brilliant results. The high mortality of pneumonia in young children limited the opportunities of seeing this result.

Mr ROMANIS, in his reply, said that it was exceedingly satisfactory that the discussion had centred more round general principles of treatment than minor details of technique. In reply to Dr Clarke's suggestion that primary suture without drainage might be employed more often, he felt that this method was more suitable for early cases of empyema in adults than in children, for in the former it was not, at any rate, likely to lead to any harm. He emphasized that he did consider there was an objection to resecting a rib in infants. With Mr Ramsey's and Mr Crumble's suggestion that the opening in the empyema cavity should be high up he agreed, and in reply to the latter's question stated that it was usually quite easy to explore the whole pleural cavity with the hand, by means of a rib-spreader, without removing a rib at all.

SECTION OF PATHOLOGY AND BACTERIOLOGY.

Professor J. C. G. LEDINGHAM, C.M.G., D.Sc., M.B.,
F.R.C.P., F.R.S., President.

DISCUSSION ON THE PATHOLOGICAL BASIS OF TREATMENT BY RADIATION

OPENING PAPERS

I.—PROFESSOR SIDALI RUSS, D.Sc.,
Middlesex Hospital.

The exposure of the body to radiation, ranging from light to gamma radiation, gives rise to changes so profound, yet different in character according to the degree of exposure and the nature of the wave-length employed, that it would appear too soon to expect any general explanation of these actions. Yet underlying their application the pathological basis becomes more and more elaborately laid.

Now may, I suppose, take it for granted that the most important therapeutic application of radium and x-rays is in the treatment of malignant disease, and, in the case of light and ultra-violet therapy, surgical tuberculosis and certain deficiency diseases. In the latter case we are dealing with radiation which penetrates a comparatively small distance into the body, yet profound effects are produced by it, while with x-rays, and especially gamma rays, there is often a widespread distribution of the rays throughout the structures of the body.

I take it that, in the laying down of the pathological foundations of such therapy, there is not only the necessity for specifying what cellular changes result from irradiation, but the no less urgent ones of correlating them with the dosage employed and indicating the processes by which these changes are brought about. In the latter case the pathologist is no doubt on physiological ground, for the processes set going by irradiation of the tissues are intimately bound up with the normal functions of the various organs. But the pathologist will no doubt be pardoned such an incursion where physiologists themselves have seemed rather shy of investigation. Perhaps the study of the normal functions of the body has left them too little leisure for investigating the upset of such functions by radiation, yet the need of this information is urgently felt.

Heliotherapy has of necessity focused attention on the indirect action of radiation. The degree to which visible and ultra-violet radiation penetrates the tissues is small, it becomes, in fact, gradually smaller and smaller as pig-

mentation due to the exposure occurs, and there is a natural tendency to attribute the reactions which occur to some effect set up either in the blood stream or of the lymph, or to suppose that the nervous system plays some important, though obscure part.

In spite of what we may call the extreme old age of this form of therapy, little is known of its essential processes, and hence its pathological basis is not so well defined as is the case with x-rays and radium. Attention will naturally be directed by others towards the various aspects of this basis, and we may then balance the evidence for the relative importance of the different processes involved. Pathological researches have shown that cellular degeneration is a frequent sequel to irradiation of tissues. This degeneration consists in various abnormal features appearing among the cells at differing times after irradiation. These changes, which have been described in great detail by various authors, are met both with x-rays and with radium. They may be due to

1. A direct action of the radiation upon the internal constituents of the cell.
2. A direct action of the radiation upon the interfaces of the cell.
3. An indirect action which irradiation initiates.

Though it is probably true that some malignant tissues are more susceptible to these rays than are the contiguous normal cells, it cannot be said that this is generally so. A damaging dose of radiation given to a malignant mass does some damage to the normal structures, and in many cases, as I have pointed out, therapeutic measures should be differently directed from what is possible when the factor of susceptibility is more favourable. The classical work of Dominici and of Cluett has shown that the subsequent course of events throughout an irradiated tumour mass is often largely conditioned by the reaction of the local normal tissues. It would be incorrect to say that the researches have clearly decided the conditions under which favourable reactions can be brought about, but their work clearly distinguishes the action of radium and x-rays from that of cauteries.

While pathologists have discovered various changes of structure undergone by the tissues after irradiation, they have hesitated definitely to attribute these either to a direct action upon the internal constituents of the cell or to some interfacial action. I should like to hear such alternatives discussed, because I think that there is much to be said for the latter playing the dominant part in the first instance, though, in the absence of direct experimental proof, this is perhaps rather speculative on my part.

If we look upon the tissues as systems involving a continuous adjustment of their equilibrium, I think that the upset of such equilibria is more likely to have a profound effect upon the composite mass than the actual breaking down of the chemical complexes within the cell. The fact that the life of the cell is so largely conditioned by the interplay of forces surrounding it, while the actual decomposition of chemical compounds is not a very striking feature of the action of x or radium rays, leads, I think, to this view. Perhaps one of the most striking facts in support of it is the special vulnerability of cells in the act of mitosis, when cell activity is at its maximum. Cells are, moreover, capable of standing a certain amount of irradiation without any naked eye or microscopical changes being detectable. It is easier to picture the cell accommodating itself to the irradiation than it is to visualize the restoration of broken down molecular complexes. Yet periodically the claim is made that the biological effects of radiation are due to the disintegration of some such complex.

Under natural conditions the surface of the body accommodates itself to light and, to some extent, to ultra-violet radiation. As far as I know, no experiments have been published showing the ranges of this power of the body towards x-rays and radium, and yet there is no doubt that it exists. Let us consider a very simple case. If the skin is exposed to a certain intensity of x-rays for fifty to sixty minutes we can produce a reaction which can be traced through the various stages of erythema, epilation, blistering, ulceration. Further, it is found that if the time

is reduced to thirty-five minutes, these stages only go as far as blistering, if the exposure is reduced to twenty-one minutes to epilation, and if the exposure is reduced to about five or six minutes there is no naked eye effect at all. This, of course, indicates the toleration of the skin, but what has this entailed? Is the skin now in a position to tolerate more or rather less radiation than before it was called upon to accommodate its function and structure to the dose? From the analogy in the case of ultra-violet light one might, perhaps, conclude that it would now need more radiation than initially to produce the same amount of damage, but that, if the initial dose had been a damaging dose the reverse would be true. Experiment or clinical experience can, however, decide these points.

Intimately connected with such accommodating power is the capacity of the skin to tolerate very slightly damaging doses, provided these are repeated at intervals which allow repair in between the exposures. Here Mr. Hudson, at the Middlessex Hospital, has found that although a certain dose can be repeated every week almost indefinitely, if it be attempted twice a week damage quickly becomes evident.

Experiments of this character appear to me to bear forcibly on the question of cell equilibrium. In tissue clearly damaged by radiation we have evidence of the whole equilibrium being upset. In tissue submitted to doses which have no visible effect whatever we have the equilibrium entirely conserved, as it is towards visible radiation and in those cases where only slight visible effects are produced, yet, with integrity of the structure, we may perhaps look upon them as stable yet entirely new conditions of equilibrium.

It is known that the various tissues respond differently to a dose of radiation ($Q \times t$) according to whether the time of exposure is short, Q being large, or long, Q being small. Lazarus Bailow was, I believe, the first to point out this difference in the columnar and squamous cells of the normal rat on exposure to radium. He found that, in order to eliminate undesirable damage, it was better to keep the quantity of radium low and prolong the time of radiation when dealing with squamous cells, while the reverse held good with columnar cells. As a result of clinical observations, Pinch concludes that malignant growths of an epiblastic character are more favourably influenced by a small intensity, acting for a long time, but the reverse is the case with mesoblastic growths.

It is still obscure why there should be a difference in the reaction of the tissues when the actual dose is constant, the only variation being in the conditions of exposure. There has been a tendency to link it up with the undoubted fact that, during a long exposure, unless prevented by the radiation from doing so, more cells would come under irradiation in a state of division, and, when in a state of division, some cells are known to be more vulnerable than in other stages of growth. I think that before accepting this basis of explanation we require proof of the following:

- 1 That the intensity of radiation used was enough for a lethal dose to be given during the actual time taken for division.
- 2 That the period of radiation extended over a period equal, or nearly equal, to the time for the cell cycle.

Though the divisions are no doubt arbitrary we may consider four stages in the cycle of operations involved in continuous growth (see diagram). The stage of growth

involves not only an increase in size but the process of maturing. When the cell is mature it goes into mitosis. We may consider Phase I as the stage in which the cell is going into mitosis, Phase II as the stage in which the cell is going through mitosis, and Phase III as the stage in which the cell is coming out of mitosis—that is, the cell is dividing, give rise to two daughter cells.

We may see by an example that similar microscopic findings, after irradiation of a group of cells, might be obtained by doses which were actually different. Let us assume that in one case we employ a dose

- (a) which is sufficient to—
stop Phase I,
do nothing to Phase II,
stop Phase III

And in another case we employ a dose

- (b) which is sufficient to—
do nothing to Phase I,
delay Phase II,
hasten Phase III

The result will be that subsequent to irradiation there will be in case (a) fewer in Phase II, more in Phase III, and in case (b) more in Phase II, fewer in Phase III. Actually the numbers of mitotic figures might be the same in the two cases, and the distinction between the two could only be made microscopically when the separate phases were recognized. On the other hand, naked-eye observation and measurement would recognize no growth in case (a), but growth, although retarded, in case (b).

This question, which is perhaps of equal interest to pathologists and radiologists, is one which I think will be discussed still more in the future, for the adjustment of the therapeutic dose to suit these particular characteristics of the system irradiated is a problem ever in front of the radiologist, and here he turns to the experimental pathologist. Only recently the striking fact has been shown by Stringer and his colleagues that when a heavy dose of radiation is given to *in vitro* growths of certain cells of the chick embryo mitosis is arrested almost at once, and there are good reasons for believing that this is true when tumour cells *in vivo* are irradiated.

The effects of radiation upon the tissues are unique—they do not in general resemble the effects upon inert media, so it seems to me that the safest guide in such exploration is not that of analogy to what occurs in ordinary gaseous and liquid media. In living tissues one is confronted with a complex which is continuously adjusting its equilibrium with contiguous or enveloping structures, and experimental methods appear to me more likely to be successful if the complex is kept in mind as such without the effort of reducing it to simple terms. One of the limitations of experiments on tissue cultures is that the cells are put under conditions different from what they would experience in the body, but this limitation is recognized by those employing the method, and valuable indications are to be expected from its use.

No doubt, for a thoroughly satisfactory pathological basis of radiotherapy, we ought to have enough information to enable us to visualize the processes involved in the irradiation of a malignant mass from start to finish, we shall have to wait for this, but, one by one, the significant processes are being recognized. There is nothing so depressing as being told that we are only at the beginning of the subject. I do not think that this is the case, but rather that we are well in the middle of it.

II—Miss M. E. HUME

THE ACTION OF ULTRA-VIOLET LIGHT UPON THE GROWTH OF RATS

It has now been known for some years that ultra-violet light is curative of rickets in both men and animals. Before that discovery was made it was already known that cod liver oil cured rickets.

When young rats are fed on a synthetic diet which is complete in fat, protein, carbohydrate, and salts, and in vitamins B and C, they cease to grow after a time and they develop symptoms of xerophthalmia and rhinitis, their bones develop imperfectly, there may be histological signs of rickets, and the animals eventually die. When cod-liver oil, containing an abundance of the complex most conveniently referred to as the "fat-soluble vitamins," is added to this diet in sufficient quantity, growth is restored, and all the other faults are corrected.

Since, then, ultra-violet light seems perfectly to substitute cod-liver oil in the cure of human rickets, it seemed of interest to find out how far, if at all, it can substitute cod-liver oil in promoting the growth of rats and in preventing the symptoms just described as occurring on a diet deficient in fat-soluble vitamins. It should also be possible by this means to discover which of the symptoms can be prevented from developing by the use of ultra-violet light, and which, if any, are controlled by another factor.

Young rats about a month old, when placed upon a diet deficient in fat-soluble vitamins, may behave in very different ways according to the light and food which the mother has received during pregnancy and lactation. This factor causes enormous variation in the amount of reserves which the little ones are able to accumulate, and thus may vastly influence their behaviour when faced with a deficiency. If the mother has received cod liver oil, the little ones may even reach maturity on the deficient diet, without showing any noticeable symptoms of deficiency. It is, however, possible to breed a very suitable type of young rat which, when placed upon the deficient diet, grows normally for about a fortnight, the rate of growth then slackens off, but growth does not entirely cease. It continues slowly for perhaps another eight weeks, then it ceases altogether, the symptoms already described appear, become acute the animal declines, and dies somewhere about the hundredth day of experiment.

If, however, we take such a young rat as I have just described, and from the moment at which it is placed upon the experimental diet we also irradiate it with the mercury vapour quartz lamp for ten minutes daily, we considerably alter the picture. Instead of growing normally only for the first fortnight of experiment, the irradiated rat continues to grow normally for a much longer period—some eight to ten weeks, then, however, growth ceases. Symptoms of eye disease appear, accompanied by rhinitis, pneumonia, and sometimes cystitis. Crimer has also described an atrophy of the intestinal mucosa, so that there is probably a very general mucous membrane involvement. Death occurs, but calcification is found to be normal.

If we proceed in the same manner as I have just described, but leave the rat on the deficient diet for two or three weeks before beginning irradiation, we find that when irradiation is started, growth, which had previously just begun to slacken off, becomes normal again, but it does not remain so for as long as when irradiation and deficient diet began on the same day, and the rat does not grow so large. If the period on deficient diet, before the commencement of irradiation, is made longer still, the growth response to irradiation is proportionately shorter, and, if irradiation is not applied until the rat has been on the deficient diet for some eight weeks, there is no growth response at all. The effect of irradiation in the last case, indeed, seems rather to be to hurry the animal over the precipice, rhinitis and xerophthalmia, which before seemed slight, may increase with catastrophic rapidity, and cause death in a couple of days.

It is therefore quite evident that light cannot substitute cod-liver oil indefinitely for the growth and well-being of the rat, and that, although calcification is being satisfactorily promoted by the light, yet the set of symptoms involving the mucous membrane is setting in and proving fatal, as some reserve is gradually used up. Some other element, of which the animal at first had a reserve, must therefore gradually become deficient, and in so doing limits growth, much more completely than the absence of light or the antirachitic factor ever does, giving rise also to the fatal symptoms. This other limiting factor appears to be the original vitamin A, but how far it is completely independent of the light or antirachitic factor we are not at present at all certain. The way in which the application of irradiation sometimes hastens the end of an animal already suffering from vitamin A deficiency suggests that there is a relation of some sort, but, on the other hand, it has been found that the liver of an animal which has ceased growing under irradiation can yet revive

normal growth, when fed to another rat, whose growth had slackened on the deficient diet, but which was still capable of responding by growth to the light stimulus. The liver of a non-irradiated rat which has ceased growing does not, however, possess this property. This observation is a most important one for it shows that the first rat, though unable to grow further itself, had been able to store up in its liver the light, or the effects of the light, and to pass them on to another rat which was still in a condition to profit by them.

Besides showing that light can bring about storage, this observation also seems to indicate that the action of light is not dependent upon the presence within the body of any substance of which a scarcity is liable to occur. One must then suppose that if the light is either absorbed by some substance within the animal body, or causes there the alteration or formation of some substance capable of transportation and storage, that substance should be one which the animal body itself can synthesize or which always occurs abundantly in any food. The substance, if such there really be, when activated by the light, can reasonably be called the antirachitic vitamin. Presumably it is such an activated body which is contained in cod liver oil.

The nature of the antirachitic vitamin or of any inactive precursor substance is at present uncertain, it appears to be fat-soluble, but it is not even absolutely certain that there is one specific substance. Antirachitic properties have been conferred upon various inactive substances by exposing them to ultra-violet irradiation, and when these substances are given as food to rats they produce the same effect as does direct irradiation. Such substances are hard, cottonseed oil, liver, muscle, milk, lettuce leaves, urine and faeces of rats, and dust, cholesterol, phytosterol, and, I believe, though I only have it from a private communication, hydroquinone. The excreta of irradiated rats are active in very small quantities, more than being sufficient to promote growth in other non-irradiated rats living in the same cage. Water could not be activated. Now the probable common factor in all these substances, except the hydroquinone, is a sterol, whether of plant or animal origin, and it does seem just within the bounds of possibility that cholesterol may be the substance within the animal body which receives the ultra-violet irradiation, but, if so, there is at present no indication of what happens afterwards, nor how the calcium metabolism is thereby affected.

In the perfectly satisfactory study of the pathological effects produced by deprivation from light or antirachitic vitamin, we want darkness and a diet in which that factor alone is wanting. That at present we are unable to supply I have already described how fatal a deficiency of vitamin A is, and it is therefore necessary, for the experimental study in rats of the pathology of light deficiency, to supply vitamin A adequately. Unfortunately the sources of vitamin A at present known to us seem to be to some extent contaminated with the antirachitic factor both being fat-soluble they tend to occur together. Green leaves, however, contain vitamin A far more abundantly than the antirachitic factor, 0.4 gram daily of summer spinach contains sufficient vitamin A to maintain a rat, without containing sufficient antirachitic factor materially to increase the calcification.

I have maintained three rats in darkness on a diet deficient in fat-soluble vitamins for four months without any addition, and for two further months with an addition of 0.4 gram of spinach a day. The diet and conditions must be regarded as very low in antirachitic influence, but the animals are still alive and in very fair condition, they grow slowly, showing that lack of antirachitic factor does not absolutely inhibit growth, but only partially—a conclusion reached before. These animals will probably show a very poor bone calcification, but they do not show any serious pathological symptoms, and as long as vitamin A is supplied they do not appear to be in any immediate danger of death. Whether their resistance to disease is seriously impaired I do not feel sure, but, as far as the rat is concerned, I am personally much more impressed by the increased tendency to respiratory disease caused by a vitamin A deficiency than by any such action of deficiency in light and the antirachitic factor.

III—A PINDY, M D, M R C P,

DIREC TOR of the Institute of Pathology, Charing Cross Hospital

SOME CHANGES IN THE BLOOD AND BLOOD FORMING ORGANS
AS A RESULT OF EXPOSURE TO X RAYS

THE effects of radiation on the blood and haematopoietic tissues are very complicated, and, in the time available, only a summary of the numerous observations can be given.

It is obviously most rational first to consider the effects of radiation on the formative tissues of which the blood represents only a secretion. It is then possible to attempt some explanation of the changes occurring in various disorders in which x rays have been used therapeutically.

The present purpose is probably best served by the acceptance of a rigidly "dualistic" attitude, that is, a view that there are two distinct varieties of blood cells—namely, those derived from the bone marrow (granulocytes and red cells) and those produced in lymphatic tissue in general (lymphocytes). Large hyaline leucocytes (monocytes) have been considered as a third distinctive variety of blood cell (Aschoff and Kiyono¹), but it is convenient and probably more accurate to regard them as being derivatives of the myeloid stem cell (the myeloblast).

The effects of radiation on the various haematopoietic tissues must now be described.

1 The Bone Marrow

The effects are essentially destructive in character, and are seen in the shape of nuclear degeneration of the essential cells, although there is no change in the adipose tissue. Regeneration is slow because there is injury to the mononuclear granular cells (myelocytes) as well as to the more mature forms. Non-granular parent cells (myeloblasts) are rarely in normal adult bone marrow, and Ellemann² has shown that regeneration of the blood normally depends mainly upon proliferation of pre-existing granular cells (myelocytes) rather than upon heteroplastic derivation from myeloblasts. So long as the dosage is insufficient to destroy all traces of myeloid tissue, regeneration, in the rabbit, is practically complete in about three weeks. It is of interest to observe that all the cells of the bone marrow appear to be equally susceptible to the action of the rays, whereas lymphocytes in different tissues vary in their liability to injury.

2 Lymphatic Glands

The results of radiation resemble those due to inanition, but occur much more rapidly. There is disappearance of the essential cells preceded by signs of nuclear degeneration, but, unlike the effect of fasting, there is no diminution in the amount of fat. There are differences between the effects of the rays on superficial and deep lymphatic glands respectively. The former normally possess a bulky cortex and relatively scanty medulla, while the latter show only a thin cortical layer. Mesenteric glands also have a large medulla which is chiefly composed of lymphatic channels. The effect of the rays is mainly exerted on the lymphocytes themselves, and therefore the changes in deep and particularly in mesenteric glands are less well marked than those in more superficial ones, but, in any case, lymphocytes in glands appear to be much more resistant to the rays than are the morphologically identical structures in the thymus.

3 The Thymus

The involution of the thymus resulting from x rays has been widely investigated by Heineke, Regaud and Clemens¹, Rudberg and others, and has been shown to be rapid and extreme.

Histologically the changes are very striking: there is pyknosis of the nuclei of the small thymic cells, which undergo complete destruction. The debris of these cells appears to be ingested by the cellular elements of the thymic stroma. It is striking that, just as in the process of physiological involution, the cortical cells are the first to disappear—that is, the areas of greatest lymphocytic condensation are the most severely affected. The corpuscles of Hassall increase in size as a result of condensation of the stroma, but ultimately many of them disappear as a result of cyst formation. The effect of these changes is a varying

degree of dense fibrosis of the organ starting from the interlobular septa. It must clearly be understood that small doses produce less vigorously destructive changes, but, in all cases, there is some amount of cell injury, although active regeneration may obliterate all traces of it within a very short time.

4 The Spleen

Changes in the spleen as a result of radiation are more difficult to interpret because considerable variations occur in response to different doses. Ziegler¹³ was able to show that, if the dosage were so adjusted as to injure the Malpighian bodies without damage to the pulp, it was possible to demonstrate the occurrence of myeloid metaplasia in the latter structure within a few days.

It is astonishing to realize that the response of the pulp cells of the spleen so closely resembles that of the bone marrow cells: neither of these structures is affected so rapidly or intensely as are the truly lymphatic ones. Thus, for example, with a dosage so great as to occasion maximum damage to the lymphocitopoietic mechanism in twenty-four hours, there is no immediate sign of injury to spleen pulp or bone marrow, and the maximum disturbance in them is delayed for several days—it is, in fact, usually noted only when the animal is already moribund. Heineke was able to confirm these observations, and pointed out that the lymphatic tissues suffered intensely without any demonstrable latent period, whereas injuries to myeloid tissue and spleen pulp arose later, and were not unless a dose sufficient to cause cutaneous reaction had been used. Aubertin and Beruand¹ reached similar results: they stated that single doses of medium intensity applied to the whole body would cause necrosis of lymphatic tissue while, at the same time, occasioning myeloid hyperplasia. They made a very important distinction between two types of leucopenia occurring as a result of radiation—namely, leucopenia as a result of extreme and generalized injury to the haematopoietic tissues, as a rule associated only with fatal doses, and leucopenia occurring in spite of myeloid hyperplasia: this is presumed to result from excessive destruction in the circulation, and is said to be a much commoner form than the previous one.

5 The Blood

It is here only possible to indicate briefly the changes in the circulating blood. The alterations occurring in the morphological composition of the blood of professional radiographers have attracted much attention, although the results observed have been somewhat variable. The great majority of investigations have shown that there is distinct reduction in the number of leucocytes, which depends mainly upon decrease of the neutrophils with consequent relative lymphocytosis. Jagic, Schwartz, and Siebenod³ have recorded many such observations, and have even been able to observe the development of typical lymphatic leukaemia in such cases, similar phenomena are mentioned by Aubertin³. The state of the myeloid tissue in the early stages is, of course, quite unknown, but the pathological condition of the blood may persist without any further change for many years, and it must, therefore, be presumed that the leucopenia cannot depend upon any gross destruction of myeloid tissue. More recent, there is distinct evidence, in the blood, that myeloid hyperplasia has occurred. Aubertin records cases in which there was well marked neutrophilia and eosinophilia. The more severe lesions resulting from long continued exposure to x rays are much better recognized—namely, aplastic anaemia. Chart I and Chart Ia show the typical changes in such a case, and it must also be added that there is complete absence of any sign of regeneration of red cells—that is, there is no poikilocytosis or anisocytosis, and no nucleated red cells are seen in the blood.

The basis of the changes occurring in the blood is still a matter of controversy and can best be elucidated by discussion of the leukaemias. Chart II shows, as has also been demonstrated by Minot² and his colleagues, that chronic myelosis is not much influenced by radio-graphical treatment inasmuch as the expectation of life is not increased, although they state that the incidence of jaundice of efficiency is greater in treated

CHART I—Cause of aplastic anaemia in professional radiographer

CHART II—The leucocyte blood picture in the case of Chart I

crises Henke is emphatic that the destruction of leucocytes by x rays is a direct effect, but Cuschmann and Guapp attempted to show that there was some formation of a leucotoxin. They demonstrated that such destruction of patients suffering from leukaemia would destroy the leucocytes of animals unless the serum was first inactivated by heat. I have satisfied myself that substances do exist in the serum of treated persons, but there is also other, more indirect, evidence of their existence. Masses of leukaemic infiltration in any situation decrease in size even when only the spleen is irradiated, and some serological explanation seems to be essential.

Arnetti has pointed out that simple destruction of cells is insufficient to account for the changes in the blood picture of cases of chronic myeloid leukaemia because there is, in such treated persons, a tendency for the re-establishment of a more normal type of blood formation after irradiation—that is, a purely destructive activity of the rays is not an adequate explanation of the changes.

CHART III—Duration of life (per 100 cases) of 200 cases of chronic leukaemic myelosis (The heavy line represents cases treated with irradiation, the light line those which received no such treatment)

changes. Perthes¹⁰ has been able to show, with a fair degree of certainty, that there was a distinct slowing of the intensity of mitosis in the cells of the formative organs after irradiation, thus, again, some restraining effect other than simple destruction was well marked. It has to be recognized that, in the bone marrow of cases of chronic myelosis, there is more than one abnormality of blood formation: there is the process which results in the emigration of immature and abnormal cells, which is the most striking phenomenon noted in films. There is also, however, another process, which simply represents an increased functional activity of the haematopoietic tissue and manifests itself

in an emigration of an unduly large number of mature, well formed cells (Pincus¹¹). The effects of radiation in the cases can, therefore, be regarded as follows:
(a) A direct effect in the form of destruction of cells.
(b) An indirect effect in the form of a more selective injury to those parent cells which are producing abnormal offspring, and
(c) Another effect in the form of a more normal regulation of the production of and emigration of normal cells.
In brief, there is a qualitative as well as a quantitative change in the haematopoietic tissues of cases of chronic myelosis treated with x rays.

FOODSTUFFS IRRADIATED WITH ULTRA-VIOLET LIGHT. THEIR EFFECT ON THE BONE LESIONS OF RACHITIC CHILDREN.
Our contribution to the discussion is concerned with one disease, rickets, and incidentally with infantile tetany or spasmophilia, both of which, in our opinion, are probably due in this country, in the great majority of cases to insufficient exposure to ultra-violet light. Clinically there are two aspects to the treatment of rickets: one must consider the effect of the therapeutic agent (1) on the general health, and (2) on calcium and phosphorus metabolism, as evidenced by changes in the bone lesions. Light usually improves both the general health and the calcium metabolism of a rachitic child, but the two effects cannot be regarded as having an identical pathological basis since they frequently do not show a parallel course. Improved calcium metabolism is not merely the result of improved general health—for example, in a case we have recently had under observation, an acute illness (an attack of pneumonia) did not retard the onset of healing of the bone

lesions or prevent the cure of spasmophilia. As regards the retention and metabolism of calcium and phosphorus cod-liver oil, containing the so-called antirachitic factor, and ultra-violet light can be regarded as interchangeable, but the same does not hold as regards the effect on the general health. Miss Hume has pointed out that ultra-violet light cannot replace all the physiological effects of light and it is perhaps self-evident that cod-liver oil cannot replace light in many of its physiological effects. Artificial light therapy (in which only the factor of increased light is introduced, thus differing from sunlight therapy out of doors) usually brings considerable general improvement in the activity, muscle tone, and contentment of rachitic infants, whereas cod liver oil has much less general beneficial effect.

We will confine ourselves to observations on the pathological basis of the action of light on the bone lesions. The x-ray photographs (intern slides were shown) illustrate the process of healing of rachitic bone lesions, induced either by light treatment or by giving the antirachitic factor in cod-liver oil. The renewal of the normal process of calcium metabolism was in this particular case brought about by exposure to sunshine out of doors in London in April, May, and June. During the retic stage of the disease the laying down of calcium in the bones ceases, osteoid tissue is formed at the growing ends of the bones, and frequently also under the periosteum. This osteoid tissue, since it is uncalcified, is invisible or scarcely visible in the x-ray plate. After an interval of two to three weeks from the beginning of treatment, shadows appear in the x-ray plate, indicating the deposition of calcium in the osteoid tissue and at the epiphyseal line, and there is a gradual change from osteoid tissue to normal bone tissue—a change which in a case of some severity may take several months to complete, even with vigorous treatment. The clinical deformities of rickets may, of course, persist a lifetime.

It seems that the identity of the influence on calcium metabolism of exposure of the skin to ultra-violet light, or administration by the mouth of cod-liver oil, is due to the fact that these are two methods by which the body may acquire the same "antirachitic factor"—that by the action of light this substance can be formed either in the cells of the living creature or in its foodstuffs, and that many substances can be imbued with the antirachitic factor by exposure to ultra-violet light. The antirachitic property may be dependent on a chemical change shown to occur in cholesterol or phytosterol under irradiation. Irradiation alters both the smell and taste of certain foodstuffs—for example, dried milk or minced meat.

We have had under observation at the Queen's Hospital for Children since February of this year rachitic children receiving a daily ration of irradiated foodstuffs in order to test the clinical value of some of these substances. We would like to take this opportunity of acknowledging the constant co-operation and help of the sisters who worked with us—Sister Francis, Sister Hook, and Sister Westbrook. The number of in-patients was necessarily small on account of the difficulty of reserving beds for such cases, but we intend to give you only the results obtained with controlled in-patient cases on account of the uncertainties attaching to observations on children in their own homes.

The technique of irradiation of the foodstuff was the same in every case. Twenty-four hours' supply of dried milk, cottonseed oil, or white wheaten flour—the three substances heretofore tested—was spread in a very thin layer in a flat dish placed for one hour under the mercury vapour quartz lamp at a distance of one foot from the burner. The lamp used was the Hanau pattern of mercury arc with burner voltage of 140, made by the Hewlett Electric Company—namely, a lamp of the vacuum type. The burner has been in daily use for many months for the treatment of patients.

During the whole period of observation there have been cases of rickets in the ward on the same diets, excepting that no part of their foodstuffs was irradiated. In all, six such cases have been under observation—but since one admitted in June was already healing at the time of admission it should be excluded, leaving five controls. Of these five, four showed during the observation period of six weeks upwards no evidence of calcification, and the fifth

none for exactly six weeks—that is, until eight days after a single exposure to the mercury arc. We conclude that in this case the calcification, which was very slight (see below, Case V C), was probably due to the exposure to ultra-violet light, so that we may say that no healing of the bone lesions occurred in any of the five controls without antirachitic treatment.

The ward is light and airy, and the children were given the ordinary ward diet except that a dried milk (a full cream milk dried by the spray process) was substituted for fresh milk. The older children received a mixed diet of meat, soup, vegetables, milk pudding, dried milk, bread and butter, and fruit. A middle group received milk pudding, bread and butter in addition to the dried milk, and the youngest group only dried milk with additions of sugar and fruit juice. Weekly x-ray photographs were taken of the long bones of each child.

Lantern slides made from x-ray photographs were shown illustrating typical cases of the series and the effect of treatment with irradiated foodstuffs on the bone lesions.

J E aged 3½ years clinically a severe case of rickets showed radiographic evidence of calcification of the bone lesions fourteen days after the beginning of treatment with 3½ ounces daily of irradiated dried milk. The process of healing progressed steadily and was nearly complete at the end of two and a half months' treatment. Two other cases on irradiated dried milk showed equally satisfactory progress. Eleven to twelve days on irradiated dried milk caused the complete disappearance of symptoms and clinical signs of spasmophilia in one of these children. The rate of calcification was approximately that usually obtained with administration of cod liver oil or with direct exposure to ultra-violet light.

V C aged a year and ten months on the same mixed diet as J E but having her dried milk untreated showed no healing for the first six weeks in hospital. Eight days after a single exposure to the light of the mercury arc there was evidence of a slight increase in the calcification at the epiphysis, but this became again stationary in spite of three months' treatment with 3 ounces daily of irradiated white flour. Another case receiving irradiated flour showed no healing after six weeks' treatment. Both cases were cured with sunlight and cod liver oil administration.

J H aged a year and three months was one of two cases healed by the administration of irradiated milk which after irradiation was boiled for ten minutes. The rate of progress was as rapid as in the children receiving the milk without boiling. It is therefore possible to cook some irradiated foodstuffs without destroying their antirachitic potency.

One child received a daily ration of 6 drachms of irradiated cottonseed oil. This quantity in several out-patient cases produced looseness of the stools, showing that the dose was near the limit of tolerance in young children. In this case there was slow calcification apparent in the x-ray plate from the thirty-eighth day onwards. An average sample of cod liver oil in a much smaller dose usually produces radiographic evidence of healing in two to three weeks, and so far as one can judge from a single case (together with indications obtained from out-patient work) it would seem that irradiated cottonseed oil in the dose of 6 drachms daily exerts a slight antirachitic effect.

To summarize. The effect of direct exposure to ultra-violet light on the bone lesions of a rachitic patient appears to be dependent upon the power of light to produce in certain substances the so-called antirachitic factor. Rapid healing of the bone lesions in children can be brought about by dried milk irradiated with ultra-violet light from the mercury arc—and this antirachitic potency of the milk withstands ten minutes' boiling. Three ounces daily of white flour similarly irradiated had little or no effect, and the antirachitic power of 6 drachms daily of irradiated cottonseed oil is probably slight. It is possible in view of certain animal experiments, that the period of irradiation (one hour at one foot from the mercury arc) was excessive, since it seems that a prolonged exposure to ultra-violet light will destroy the antirachitic potency. A shorter exposure has imparted.

It seems probable that the action of a foodstuff artificially rendered antirachitic by irradiation with ultra-violet light is identical with the action of a naturally occurring foodstuff containing the antirachitic factor, and that no more beneficial effect is to be expected from irradiating a patient's milk than from giving cod-liver oil. But when cod-liver oil cannot satisfactorily be given irradiated substance may in the future prove of considerable value.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CONCURRENT HERPES ZOSTER AND VARICELLA

The occurrence of these two conditions in the same patient at the same time seems to me to be of sufficient rarity to attract attention.

On May 19th last I saw a boy, aged 7 years, who five days previously had complained of pain in the upper part of the left side of the chest, on the following day a rash appeared in this area. On examination there was an extensive patch of herpes zoster affecting the third left dorsal nerve, extending from the mid line behind to the mid line in front, the area was as much as 3 inches wide in places. Further there was a well marked rash of chicken-pox over the body and limbs, all stages of the rash being present. There was a history that there had been a few vesicles round the hips a few days before, but these were not present on examination. There were no other cases of chicken-pox or shingles in the family and the boy had not suffered from either condition before.

This case (which I report by permission of Dr. A. P. Thomson) seems to lend some support to the theory that the two conditions are due to the same cause.

GROFFER DEDRY, M.B., M.R.C.S.

Children's Hospital Birmingham

INCUBATION PERIOD OF VARICELLA

The following case is of interest in that it would appear to indicate that the incubation period of chicken-pox may, in the case of an infant, be as short as nine days.

On May 10th I was asked by Dr. D. D. Anderson of this town to see a mother and baby suffering from chicken-pox. Dr. Anderson had fifteen days previously attended the woman in her confinement. Mother and baby then appeared quite well. On the tenth day after birth the infant developed well marked chicken-pox and three days later the mother developed a similar rash. The mother had no preliminary illness beyond a slight headache which passed off in the course of a few hours.

When I saw the cases the rash was well developed, centripetal in distribution while constitutional effects were apparently nil. The mother had been vaccinated in infancy and showed no mark. The woman's mother had been present at the confinement and on the following day a sister aged 9 visited the house. During the time this young girl was in the house it was noticed that she had a few spots which were subsequently diagnosed as chicken-pox.

M.O.H. Stockton-on-Tees

SUPPURATION IN A HYDATID CYST OF THE LIVER OPERATION RECOVERY

The following case, which was under my treatment recently, seems of sufficient interest to merit publication.

A Hindu patient aged 30 was admitted to the Pachamba Mission Hospital on March 28th 1925 with a history of fever, pain in the right hypochondrium and progressive emaciation of about six weeks duration. The liver was enlarged in a downward direction to the extent of two fingerbreadths below the costal margin, the enlargement being semi-circular in outline and tender on pressure. There was no jaundice. The patient's condition and the fact that he gave a history of an attack of dysentery two years previously indicated a strong probability that the hepatic enlargement was due to an amoebic abscess. He was accordingly treated with daily hypodermic injections of emetine hydrochloride gr. i for ten days. This had no effect on the temperature which showed an evening rise to 103.104° and the liver enlargement increased in extent gradually assuming the form of a dome-shaped swelling. By April 13th the swelling had become definitely fluctuant and the liver dullness had extended upwards to the level of the fourth costal cartilage. The transmission of cardiac pulsation could be felt over the lower part of the right side of the thorax.

Operation

On April 14th under ethyl form anaesthesia the enlarged liver was exposed by an incision 3 inches long extending downwards from the costal margin and the exposed area was isolated from the peritoneal cavity by gauze packing. The liver was explored with a hypodermic needle and a syringe of thin pus was aspirated. The needle was withdrawn and the liver incised. The evacuation

of a large amount of pus containing numerous small cysts cleared up the diagnosis, and proved the condition to be due to suppurative infection with a hydatid cyst of the liver. Fibrinous fragments of the broken down capsule of the mother cyst were also evacuated, and the "daughter cysts" varying from the size of a cherry to that of a golf ball must have numbered well over fifty. A cigarette drain was inserted into the abscess cavity and sutured to the abdominal wall.

There was profuse discharge of pus and bile for several days and on April 30th a number of daughter cysts and fragments of cyst wall were evacuated. After this convalescence proceeded steadily. The wound was healed by June 6th and the patient was discharged from hospital a few days later, in good health and having gained considerably in weight.

DIATHERMY IN PROSTATIC ENLARGEMENT

I want here to call the attention of those medical men practising diathermy to the very valuable method (if they have not already tried it) we possess in diathermy for relieving enlargement of the prostate. There are very many cases in which surgical procedure is inadvisable because of possible cardiac trouble, age of patient, etc. The method I adopt is to use a metal intracanal electrode with an oblong handle, this is warmed, introduced, and pressed against the gland, the indifferent electrode is placed on the abdomen, or, better still, under the hip. The regulator of the diathermy apparatus is at zero, the current is gradually increased until about 15 amperes is reached. The first session is limited to about eight minutes, it is repeated daily for several days, then every other day, gradually increasing the intervals between treatments. My experience has been that the patient experiences immense relief, the discomfort appreciably and quickly lessens, and life is made worth living in the case of men so afflicted in their declining years who would otherwise be doomed to chronic invalidism.

C. J. ST. ANDREW'S

STRANGULATED HERNIA CONTAINING OVARY AND FALLOPIAN TUBE IN AN INFANT

The following case is interesting in that inguinal hernia is rare in females, especially at such a tender age. Strangulation in such circumstances must be very rare. That the case was congenital is obvious, it is worth of note that there was no associated congenital deformity present in the parietal cleft palate.

A female child weighing 7 lb, born in King's College Hospital was unable to suck owing to a cleft of the soft palate. Whilst the mother was in hospital her milk was drawn off by means of a breast pump and given to the child. When aged seven weeks the child was brought back to hospital because the mother had noticed a lump in the right groin a few days before. At first it had disappeared when the child went to sleep, but it reappeared on crying. The child had been weaned and had lost 14 oz since birth. This lump the size of an acorn was situated in the crease of the right groin above and internal to the pubic spine. It was tense and irreducible, no expansile impulse on crying was detected, translucency could not be demonstrated. Percussion in such a case was of little value. The child was placed in a bed the foot of which was raised and evaporating lotions were applied locally. At first there was no constitutional disturbance, feeds were taken well and the temperature and pulse were normal. The next day the child became restless it cried a great deal and drew its legs up upon the abdomen, the pulse rate increased and the temperature was just subnormal, there was a small action of the bowels. The swelling had increased almost half as much again and was very tense, palpation was greatly resisted.

Operation revealed a well formed sac reaching down into the inguinal ring, the narrow neck was at the external inguinal ring. On opening the sac some fluid escaped, contained within were the right ovary and Fallopian tube intensely injected, oedematous and purple red. After dividing the constriction at the neck of the sac and applying hot saline solution most of the injection disappeared so that both organs were returned into the abdominal cavity. The neck of the sac was transfixed and tied, the fundus removed and the inguinal canal obliterated by two catgut sutures. The skin was closed with silk-worm gut.

The child did very well. Owing entirely to competent nursing it had gained 6 oz when discharged.

I am greatly indebted to Mr. Cecil P. G. Walcott for allowing me to operate upon and publish this case.

Reviews.

"MANSON'S TROPICAL DISEASES"

THE world is apt to forget the great men by whose genius and labours wide regions, rich but pestilence-ridden, have been opened to the farmer and pastoralist. No one gave so great an impetus to the serious study of tropical diseases by modern scientific methods as Patrick Manson. Not only was he himself an indefatigable student of the clinical characters of these diseases and of their pathology and etiology, being in the two subjects last named greatly helped by an intimate acquaintance with their epidemiology, but he was from the first anxious that others should continue and extend his researches. From the time he returned from the East to this country he was determined that the knowledge gained should be popularized, using that term in its best sense. To this end he followed two distinct but parallel lines of policy: the first was to interest the administrator at home and abroad, and the second to give to the medical men who were to be the executive officers of the administrators opportunities for learning what was known. He therefore prepared a *Manual of Tropical Medicine*, and with the help of Mr. Joseph Chamberlain established the London School of Tropical Medicine. The school will keep his memory green, and the pious cure which his son-in-law, Dr. Manson-Benn, has devoted to the production of the new edition¹ of the manual will help in this direction.

It was no light task to prepare the first edition of the manual, which was published in 1893, for it was practically virgin ground that had to be broken, and Manson had no precedent to guide him in its arrangement. The introduction written by him for the sixth edition has been retained by the editor of the eighth, and it is to be hoped that it will not be omitted from any subsequent editions. The book has been thoroughly revised, but the work has been so well done that there are fewer pages than in the seventh edition.

The article on medical zoology (with a section on snakes by Miss Procter) now occupies 190 pages, and the forty pages on laboratory methods will be useful to those who have to travel light. Many new illustrations have been added, and the coloured drawings are a striking feature of the book. There are also maps showing the geographical distribution of trypanosomiasis, leishmaniasis, yellow fever, schistosomiasis, and filariasis. There is a brief section on infections by *Bacillus coli*, and this rather tempts one to ask why tuberculosis and other world-wide diseases should have been left out. The question of what should be included in a manual of tropical diseases is of course a matter of opinion, and Sir Patrick Manson's own definition may well continue to be the guide. The plan Manson adopted in dealing with each disease under etiology, pathology, symptoms, and differential diagnosis, has been continued, and undoubtedly has its advantages, though some would perhaps prefer to have symptoms and pathology side by side.

There are so many people who still, whenever they exhibit a rise of temperature, think they are suffering from "malaria" because they were infected many years previously, though they have not had any subsequent reinfection, that a note on the duration of latent malaria with any statistics available would be of very real interest and help to the profession and to the public.

The book is eminently readable, and the illustrations, paper, type, and printing are good but it remains portable. The book is not an encyclopaedia, but a handbook, and the ideal of returning it as an introduction to the subject—a textbook for the student, a practical handbook for the worker—has been excellently well maintained.

THE ENGINES OF THE HUMAN BODY

IN the second edition of Sir ARTHUR KEITH's *Engines of the Human Body* the text of the first edition has been reprinted with merely verbal alterations, but at the end of the volume there is added a series of thirteen appendices, running in all to upwards of fifty pages, in which an account is given of the knowledge of the mechanism of the human body gained since 1919. The plan permits of the reader seeing at once the directions in which our knowledge is extending and at the same time allows of the larger volume being published at the original price. The appendices open with a very graceful tribute to the late Sir James Dewar, who was for so long the director of the Royal Institution, at which the lectures which form the basis of the book were originally delivered. The remaining appendices deal with such subjects as the phenomena of muscular contraction, the nerve control of muscle, vitamins, insulin and hormones, the nourishment of cartilage, the output of the heart, and the effect of barometric pressure on mental and bodily function, in which the recent work of, amongst others, Professor A. V. Hill, Sir Charles Sherrington, Sir F. G. Hopkins, Professor E. Mellanby, Dr. Barcroft, Professor Cathcart, Dr. John Haldane, and Dr. Banting is laid under contribution.

The observation suggests itself that, while it is apparently a relatively easy problem to correlate the processes of the human body with those of mechanical engines and instruments, this only applies to gross effects, for the moment we look beneath the surface and study them in their subtler action we at once see what would asunder they actually are. The attempt Sir Arthur Keith has made to correlate them has brought out their fundamental differences and has so served a purpose of the highest value. The work furnishes us with an admirable survey of all that is known on the subject of the actions of the human body, and will be found of very great interest to all those—and are there any others?—who are concerned with the question.

THE GROWTH OF THE JAWS

THE Dental Board of the United Kingdom has published, under the title *The Growth of the Jaws, Normal and Abnormal, in Health and Disease*,² a series of five lectures delivered under its auspices by Professor E. Fawcett of Bristol (development of the bones around the mouth), Professor Birch of Birmingham (the growth of the jaws and palate, and the genesis and growth of deformed jaws and palates), Mr. George Northcroft (the teeth in relationship to the normal and abnormal growth of the jaws), and Sir Arthur Keith (certain structural changes which are taking place in our jaws and teeth).

The project is ambitious, and the individual lectures worthy of all praise, but we have to confess to a feeling of disappointment that no definite conclusion is reached on the vexed question of the genesis of the so-called adenoid mouth, as Sir Arthur Keith summarizes in concluding his lecture, there is a feeling of disappointment because he tells us nothing which can be of use to us in practice. But this feeling quickly vanishes, giving place to a lively appreciation of the persistent endeavours of those who are seeking to elucidate one of the most difficult problems of human biology.

Professor Fawcett uses human facts almost exclusively, and is to be congratulated on his excellent choice of material. His description of the development of the vomer and of the palatal cartilages may perhaps help to an understanding of "deviated septum." We wonder whether his researches will supply an explanation of the occurrence of carcinoma originating in the bone beneath the orbit?

Professor Birch's two lectures offer us, besides their intrinsic interest, the advantage of a reasoned criticism of

The Engine of the Human Body. By Sir Arthur Keith, M.D., F.R.S., F.R.C.S. Second edition, completely revised and enlarged with new appendices added. London: Williams and Norgate, Ltd. 1925. (Demy 8vo pp. xiv + 343, 47 figures, 2 plates, 12s. 6d. net.)

² *Five Lectures on The Growth of the Jaws, Normal and Abnormal in Health and Disease*. Delivered under the auspices of and published by the Dental Board of the United Kingdom. London, 1924. (Roy. 8vo, pp. vii + 147, 5s. net.)

¹ *Manson's Tropical Diseases*. Edited by Philip H. Manson-Bahr, D.S.O., M.A., M.D., D.T.M., and H. Cantab, F.R.C.P. (Lond.). Eighth edition revised. London and New York: Cassell and Co., Ltd. 1925. (Demy 8vo, pp. xx + 895, 6 maps, 20 coloured plates, 7 half-tone plates, 287 figures, 38 charts, 31s. 6d. net.)

Sir Arthur Keith's and Mr J. Champion's recent paper on the growth of the jaws. We may be allowed a doubt whether he is right in his summary rejection of aduoids and mechanical influences as productive of jaw deformities. A fuller acquaintance with clinical facts might alter his views. Jaw deformities do not, as Professor British assumes, necessarily first make themselves strikingly evident at the time of the change of the teeth. They are often obviously and even strikingly present some years sooner, and can always be foretold by observation of a failure of growth of the maxilla, there are clinical facts of daily occurrence to indicate the mechanical powers of compression of the lips and cheeks.

Mr George Northeroft gives a valuable table of measurements showing that small deciduous teeth may be expected to be followed by small permanent successors. For this work, laborious and carefully executed, he will be heartily thanked by every dentist.

Sir Arthur Keith supports the thesis that definite changes of a measurable amount are affecting our teeth, jaws, noses, orbits, cheeks, and other parts of the structural conformation of our faces, but adds that they are not affecting everyone. An edge-to-edge bite of the incisors is the rule with ancient British peoples, as compared with our present overlap of the upper in front of the lower incisors. Third prominent molars were far less frequently absent. Contracted and irregularly developed palates are never seen in ancient skulls—but are they then a discrete change, or truly a developmental change? In spite of the fact that so little seems to apply to our daily practice, every thoughtful dentist will be grateful to the Dental Board for bringing together this series of lectures.

ANATOMY

IN the new (sixth) edition of Dr WILLIAM DAVIS's *Applied Anatomy*,⁴ edited by Dr G. P. MULLER, the applications of anatomy are considered in their widest aspect. The result is a book which partakes of the triple nature of a textbook of anatomy, of surgical pathology, and of operative surgery. It is a large volume of over 600 pages with 631 illustrations, most of which are coloured. Such a book, while it contains a great deal of very important and accurate information, suffers in that by its nature it is not always precise enough for the anatomist, thorough enough for the pathologist, or detailed enough for the operating surgeon. It is intended, we imagine, for the good all-round surgeon rather than for the specialist, and as an advanced student's manual rather than as a book of reference. The chapters dealing with cranio-cerebral subjects, with the anatomy of the upper abdomen, with fractures and dislocations, are particularly meritorious. The figures illustrating the displacements in these last two mentioned injuries are perhaps the most illuminating we have seen in any general textbook. We should like, however, to draw the attention of the editor to certain corrections and additions which we venture to think might be made in future editions, for such editions we feel will be indubitably demanded in view of the excellence of so much of the text and of so many of the illustrations. In figure 43, for example, a much larger area of the occipital cortex is allotted to visual function than is usually allowed, and no account is taken of the limiting nature of the sulcus lunatus. In the same figure the motor area for the trunk is placed quite rightly in the precentral convolution but in the following figure it is situated in the superior frontal convolution. In figure 45, again, the visual area is represented as stretching along the internal parieto-occipital fissure instead of along the external fissure. The important facts that the iliacus muscle crosses anteriorly the sacro-iliac joint and that the upper portion of the transversalis muscle remains muscular up to, or very nearly up to, the linea alba fail to be correctly represented. The ampulla of Vater is shown in figure 431 on the proximal side instead of on the distal side of the union of the common bile duct and pancreatic duct. The perirenal fascia of one side is stated on page 432 to be continuous across the midline with the perirenal fascia of the other side, a view which has recently been strongly controverted.

⁴ *Applied Anatomy*. By WILLIAM G. DAVIS, M.D. Edited by GEORGE P. MULLER, M.D. Sixth edition. London: J. I. Lippincott Company, 1925. (Sup. roy. 8vo pp. xii + 638. 64 figures. 42s. net.)

The one departure into comparative anatomy among the illustrations shows the pectoral girdle of an eagle with the coracoid bone labelled "precoracoid." Among omissions, or rather among matters to which greater prominence might have been given, are the important anatomical considerations involved in mobilization of the rectum, the variations which occur in the arrangement of the extraleptate biliary passages and the accompanying blood vessels, and, in view of its great importance, is shown by Kavanagh's work, the arrangement of the peritoneal spaces in the hand. Despite these failings, which are really trifles in so large and comprehensive a book and which have been brought together rather for correction in future editions than by way of serious adverse criticism, our opinion of the work remains a very high one, and we have no hesitation in strongly recommending it for a place on the bookshelves of the general surgeon.

Dr I. B. JAMIESON's little book, *A Companion to Manuals of Practical Anatomy*, has reached a second edition.⁵ As in the first edition the Byle nomenclature, or an English translation of that terminology, has been used throughout, but for the sake of the student unaccustomed to B.N.A. terms the old names are frequently inserted in brackets. The general arrangement of the second edition follows the plan of the first, and but little change has been made in detail. The book remains an easily portable textbook of medical anatomy, popular with students because of its condensed language and clear expression.

NOTES ON BOOKS

The Journal of Helminthology, edited by Professor R. T. LLEWELLYN, I.R.S., and published by the Institute of Agricultural Parasitology at the London School of Hygiene and Tropical Medicine, has reached the fourth number of its third volume. The articles published in it are of a very specialized kind, but this number contains one observation which may have a certain interest for medical readers. Mr D. O. Morgan, B.Sc., a field officer of the institute, is engaged in observations on animals slaughtered in the Aberystwyth abattoir. Lambs invariably harbour large numbers of intestinal worms whereas sheep are comparatively free. One lamb examined in August contained twelve individuals of one species of worm, seventeen of another, seventy-nine of another, seventeen of another, and twenty-two of another, and was also furiously heavily infected with six more parasites. This, it is stated, is by no means exceptional, and the lamb was not in low condition when slaughtered. A large number of observations were made on carcasses, but no definite relation was found between the amount of fat present and the number of helminths the host contained. Very heavy infection, especially with one or two species, however, was often associated with a low condition. A two-year-old wether fed on the same pasture as the lamb mentioned and slaughtered on the same day contained none of the larger worms and only a "fair number" of two species of other worms. The observations make it probable that lambs are exceedingly liable to heavy infection and tend to become immune as they grow older and to lose the greater part of the worms picked up during their first summer.

On January 31st (p. 26), a review was published of the first edition of *Recent Advances in Medicine* by Drs. BEAUMONT and DODDS, and the success was anticipated for it has been such that a second edition⁶ has already been called for. The authors in the course of revision have expanded and illustrated their description of the colorimeter, many more tests have been added, and considerable additions have been made to the sections dealing with glycosuria and gastric analysis. In a new chapter the Dick test for scarlet fever is described at some length.

The seventh edition of *Wheeler's Handbook of Medicine*,⁷ edited by Dr JACK, shows an increase in size over the previous editions, and alterations have been made in the classification of diseases. The sections on cardiac and on nervous

⁵ *A Companion to Manuals of Practical Anatomy*. By I. B. JAMIESON, M.D. Second edition. Oxford Medical Publications. London: H. K. Lewis, 1925. (Fcap. 8vo pp. xxvi + 558. 8s. 6d. net.)

⁶ *Recent Advances in Medicine*. By C. E. Beaumont, M.A., D.M.Oxon. F.R.C.P., D.I.H. Lond., and E. C. Dodds, Ph.D. M.B. B.Sc. Lond. Second edition. London: J. and A. Churchill, 1925. (Extra pp. 8vo pp. i + 364. 40 figures. 10s. 6d. net.)

⁷ *Wheeler's Handbook of Medicine*. By WILLIAM R. JACK, B.Sc. M.D. F.R.F.S.G. Seventh edition. Edinburgh: E. and S. Livingstone, 1924. (Crown 8vo pp. xi + 629. 30 figures. 12s. 6d. net.)

diseases have been enlarged, and the articles on diabetes mellitus and jaundice have been largely rewritten. A careful revision of the whole book has been effected, and it retains its characteristics of concentration and lucid description which have rendered it in the past so valuable to medical students.

Dr HENRI LECLERC's book on the fruits of France⁸ is a fascinating study which, as its subtitle suggests, will appeal at once to the dietitian, the therapist, and the medical historian. The work consists of a series of short chapters, each of which is devoted to the consideration of one or more of the fruits which grow on French soil. The book is written in a charming style in which learning, humour, and practical medicine are cunningly blended.

⁸ *Les Fruits de France. Historique, Dietétique et Thérapeutique.* Par Henri Leclerc. Paris: Masson et Cie, 1925 (5½ x 8½ pp 274 Fr 12).

PREPARATIONS AND APPLIANCES

The Chlorine Gas Process for Sterilizing Swimming bath Water

A CORRESPONDENT informs us that chlorine gas is being employed for the sterilization of water in place of sodium hypochlorite and bleaching powder (calcium chloro hypochlorite), one of its applications is for the continuous operation of swimming baths so as to enable the same water to be used for twelve months at a time. A measured trace of chlorine gas is applied with the aid of the Chloronome apparatus of the Paterson Engineering Co., Ltd. of London, the chlorine being supplied in cylinders. The general principle of the treatment is to circulate the water continuously by means of a steam or motor driven pump passing it first through a rough gauze strainer to arrest any large objects and then to treat it with an alumino ferric coagulant, so as to separate all the colouring matter and impurities. The water is next passed through Paterson closed pressure sand filters with dished top and bottom and compressed air cleaning, using a steam injector to provide the air blast; the resulting water is then aerated, using a closed aerator with the air under pressure. Finally, the water is treated with a measured trace of chlorine gas by means of the chloronome using about 1 part per 2,000,000 parts of water; the water is returned to the bath through a steam heated calorifier to maintain a constant temperature, say about 72° F in summer and 78° F in winter; the movement of the water being imperceptible to the bathers. A detailed analysis of water treated in this way at the St. Helens public baths after nineteen weeks running when thousands of bathers had passed through showed we are informed 112 bacteria per cubic centimetre on gelatin in three days whilst *B. coli* and *B. enteritidis sporogens* were entirely absent in 100 c.c.m. nitrites and free chlorine were absent also; the free ammonia was 0.0046 and the albuminoid ammonia 0.0058 per 100,000.

PRESERVATIVES IN FOOD

REGULATIONS ISSUED BY THE MINISTRY OF HEALTH

The new Regulations regarding preservatives in food which were published in draft in February, to give opportunity for criticism, have now been issued in their adopted form by the Ministry of Health. This result has been reached after what may be regarded as a normal progress from initiation to accomplishment, in matters of Government control, where many and diverse interests are concerned. The subject is of more importance in this than any other country, because of our quite exceptional dependence on importation for the supply of foods of many kinds. Some of the most essential articles of diet come from the most distant parts of the globe, and yet should reach Britain without having undergone any seriously deleterious change. Much home produce also requires protection against injurious influences in order that it may come to the consumer in safe and sound condition. Yet we have lagged behind most foreign countries in dealing effectively with the subject. In 1889 a committee was appointed to inquire regarding preservative and colouring matters, but no action was taken on the report. Ten years later Regulations were issued by the Local Government Board, and since 1908 foreign meat, and milk and cream, have been brought under some measure of control.

The very competent departmental committee appointed in July, 1923, issued its final report towards the end of last October. Its conclusions and recommendations have naturally been of much interest, and a cause of anxiety to food traders, and have been the subject of many questions in Parliament. Shortly stated, the committee is of opinion that cold storage should take the place of preservatives. But in equipment for cold storage this country is woefully

deficient, largely owing to the cost of motor power, as compared with natural sources of such power available in various places abroad. Methods of land transport also are defective in cold storage, no doubt because chemical preservatives have stood in the way of realization of the need for improvement. It may be assumed that the new Regulations will stimulate effort to overcome the difficulties that undoubtedly exist. In the homes of the people a similar effect may be looked for. As regards milk, pasteurization before sale will continue to be a main security, but both for it and other foods greater attention will come to be paid to coolness and cleanliness of the holder, however limited such accommodation may be in the smaller houses.

The Minister of Health, in the Regulations now issued, appears to have given very fair and reasonable consideration to representations as to possible hardships. Time is to be allowed for the clearance of existing stocks, and for adjustment of methods and processes. Also Mr Neville Chamberlain indicates to the local authorities that they ought to use discretion before instituting legal proceedings in the early days of the operation of the new rules. As regards the applicability to food preservatives of the defence of warranty available under the Sale of Food and Drugs Acts, it has been found that owing to legal difficulties this would not be practicable. Attention, however, is drawn to the fact that a local authority may proceed against the manufacturer or wholesaler instead of, or in addition to, the retailer, and that this provision may advantageously be applied where articles are put up in sealed containers bearing a name and address showing where the product came from. Every grocer's shop affords evidence of the great extent to which that kind of package sale now prevails.

The Regulations themselves demonstrate that the Minister has definitely concluded, notwithstanding all opposition, to give general effect to the report of the departmental committee, whilst he has paid careful heed to the representations of the objectors. Chemical preservatives are not entirely debarred. A schedule appended to the Regulations specifies a series of articles, seventeen in all, to which sulphur dioxide, including sulphites, or in a few cases benzoic acid or benzoates, may be added in proportions stated in the schedule. The articles include sausages, fruit (fresh or dried), unfermented grape juice and non alcoholic wines, cordials and fruit juices, jam, sugar, gelatin, beer, cider, alcoholic wines, and sweetened mineral waters. Ordinary metallic colouring matters containing arsenic, copper, mercury, lead, etc., are debarred, also gamboge and some coal tar colours. The due labelling of foods containing permitted preservatives is required, and both the preservative and its percentage are to be stated. Labelling is not to be necessary in hotels or restaurants.

As regards allowable preservatives, the main protests by traders have been in respect of the exclusion of boric acid from all foods. Up till now it has been debarred from milk only, whilst its presence in cream has had to be declared, but in future it is not to be used in any article for human consumption. The assertion that injury from its use is not proved has been insufficient to secure its retention. Boric acid has a cumulative action, and it is better to practise rigid cleanliness in the manufacture of food than to trust to an agent capable of counteracting or concealing possible uncleanness. It is very satisfactory that the Minister has had the courage to act on the recommendation of the departmental committee in giving effect to this important principle.

The Regulations are to come into operation generally at the beginning of 1927 but not until a year later as regards butter and cream. At present some articles of food contain as an ingredient preserved bacon, lard, margarine, or butter, and for such articles the Regulations take effect from the middle of 1927. These details help to show how carefully the effects of the Regulations have been considered prior to their issue. The hope of all concerned will be that by co-operation of manufacturers, distributors, and consumers the difficulties which are feared will not to any great extent be realized, and that in so far as they do arise they will be quickly and effectively overcome, so that the purity of the national food supply will reach a higher standard than hitherto it has ever attained.

British Medical Journal.

SATURDAY, AUGUST 22ND, 1925

THE TREATMENT OF FRACTURES

MORE than one of the discussions in the sectional meetings at Bath which we are now publishing were of great value and likely to have far-reaching results, and among them none, perhaps, was of more importance than that on the treatment of fractures, with special reference to its organization and teaching, at a joint meeting of the Sections of Surgery and Orthopaedics. The full report is printed in this issue (p. 317). It will be remembered that on May 16th we published (p. 909) a report of a lecture on this subject delivered by Sir Robert Jones in Liverpool, in which he severely criticized the existing state of things in the great teaching hospitals, and propounded the outline of a scheme for its improvement. Knowing well that you cannot make revolutions with rose water, Sir Robert stated his case as strongly as possible, because what he and others desire is in fact almost a revolution in hospital methods of coping with these injuries. For although in certain hospitals steps have been taken in the direction desired by him, in a large number, including some of the most important, no change has been made in the methods in vogue before the war, notwithstanding the object lessons which the special surgical hospitals afforded during and after the struggle. In a leading article in the same number of this JOURNAL, commenting on the contentions of Sir Robert Jones, attention was drawn to the solution of the problem which had been found to work so well at the Massachusetts General Hospital in Boston, as described in Dr. Wilson and Mr. Cochrane's book on fractures. Mr. Gask, who opened the discussion with an address conspicuous for its moderation and fairness, took strong exception to the statement in our article that most surgeons to general hospitals must be classed as abdominal surgeons. A glance at the programme of subjects for discussion at any meeting of a surgical society, such as the International Society of Surgery or the Surgical Section at Bath itself, will, we believe, justify our statement, and if for "the abdomen" we were to substitute "the cavities of the body" the word "most" would seem to be almost superfluous.

Mr. Gask may be presumed to have appeared as spokesman for the general surgeons to many of the hospitals to which medical schools are attached, and he is himself a teacher of eminence in one of the greatest of them, and an author of one of the best textbooks of surgery. The admission, coming from such a source, that something is lacking in our teaching and our way of treating fractures, and that a considerable amount of crippling results, and therefore that all is not well, but that reforms are necessary, at once reduced the questions at issue to one of how to reorganize treatment and teaching in the manner most beneficial to the patient and most efficient for the student. But Mr. Gask did not disdain the old argument which may be called "the thin end of the wedge" which has been used for at least half a century against proposals to form special departments of surgery, as it has been in politics against all manner of reform. Yet, as a subsequent speaker

reminded the meeting, the section on fractures in Gask and Wilson's *Surgery* was written by an orthopaedic specialist.

Admitting the need of a change, and coming to the question of what the remedy is to be, we are struck, in studying this discussion, with the extent to which speakers relied upon *a priori* arguments and neglected the evidence of actual facts which effectually dispose of some of those arguments. An outstanding exception was Dr. R. B. Osgood of Boston, who as a visitor made one of the best thought out and best delivered contributions to the debate. Dr. Osgood is one of the most distinguished orthopaedic surgeons living, with a wide and very exceptional knowledge of current practice throughout the world. He told the meeting that in the United States, so far from the segregation of fracture cases having increased specialism, it had had the opposite effect, and had created a much wider interest in such cases. Using a striking chemical metaphor, he said that the reform "had added a reagent which had dissolved some of the precipitate thrown down by the specialities, and made it again a part of the general solution."

Mr. Gask put his finger on a sore spot when he said that lack of beds prevented adequate treatment of fractures. The comparatively short time for which any case can be allowed to occupy a bed in our general hospitals has undoubtedly largely contributed to the apparent preference held by the general surgeon for cases which need little or no after-treatment. A case of abdominal section may be sent to a convalescent home as soon as the skin incision is healed, but a case of fracture needs supervision for weeks after the infliction of the injury. Thus the successes of Listerism, which in so many instances have greatly reduced the amount of treatment required after the proceedings in the theatre, have resulted in diverting attention from the necessity in such a condition as fracture of careful and thorough after-treatment. When Sir Arbuthnot Lane introduced his method of plating fractures, the general surgeons were enabled to practise it for this very reason—that the whole treatment seemed to consist of a cutting operation, so that after a week or two the limb could be put up in plaster and the patient discharged from hospital. Thus we find ourselves face to face with the difficulty caused by the lack of hospital accommodation, the Voluntary Hospitals Commission, an analysis of whose report appeared in our last issue (pp. 305 and 299), has estimated the number of additional beds required in England and Wales for the proper treatment of the sick and injured of the community to be not less than the large total of 10,000.

One speaker after another in the discussion, whether a general or an orthopaedic surgeon, stated his conviction of the need of a change, but many did not insist on the transfer of fractures to the orthopaedic department. The general feeling seemed to be that great advantage would be gained by segregation of cases in a special ward, with a well taught and experienced sister and nurses, but that the treatment in such wards should be under the care of general as well as orthopaedic surgeons, the essential being that the surgeon should be really interested in the work. Mr. Fullerton's statement of the results obtained by him and his colleagues in Belfast shows what may be done by general surgeons who possess the necessary qualifications. The interests of the patient must always outweigh those of the medical student, treatment must come first and teaching follow, but the better the treatment the better the teaching, as Mr. Wade of

Edinburgh pointed out in his eloquent and instructive contribution to the discussion

It is, however, unnecessary to insist further on the need for change when we have heard from Mr Gask, who was in some degree the apologist for things as they are, that he "would welcome the foundation of a special hospital in London for the treatment of fractures under the care of specialists, a hospital in which the best methods could be shown, and from which light would spread." Even thus is conservatism wounded in the house of its friends!

TOWARDS A SOLUTION OF THE POST-GRADUATE PROBLEM

A fortnight ago (August 8th, p 266) we gave particulars of the new committee appointed by the Minister of Health "to draw up a practicable scheme of post graduate medical education centred in London, mentioned that the Minister of Health would himself act as chairman, and gave the names of the other members. It will have to encounter many cross-currents, but we may hope that it will find it possible to steer a straight course. The whole story is rather complicated, going back to the armistice, and, indeed, earlier. We will not run the risk of wearying readers by repeating it, but the new committee will start from the point where the matter was left in May, 1921, by the Athlone Committee, which recommended that a school attached to a hospital centrally situated in London should be devoted solely to post graduate medical education, and that it should be a school of the University of London, receiving substantial financial assistance from the Treasury through the University Grants Committee.

The body which primarily ought to be interested is the University of London, but in spite of good intentions, unofficially expressed it has, so far, done nothing. Several Ministries are more or less directly concerned. At the meeting summoned by the Fellowship of Medicine last March statements were made by representatives of the navy and army on the arrangements made by those services for their medical officers, these arrangements seem to be regarded as adequate, but the conditions in these services are so special that they afford little guidance for the solution of the larger problem presented by the civilian profession. Every credit is due to the Fellowship of Medicine for its persistent efforts to supply the need, but, as Sir Thomas Horder said during the discussion to which we have referred, it was a severe blow to post graduate teaching when the deans and committees of the majority of undergraduate schools withdrew their active interest. What was wanted, he said, was a local habitation where tuition could go on by demonstration and lecture, and a hostel, where men from overseas or from the provinces could reside during their stay for post graduate study or at any rate in office by which they would be referred to places of comfortable lodging.

The action of the Minister in appointing a committee in 1921 and again this year has shown that the Ministry of Health recognizes that it has a responsibility, primarily perhaps because it is the central administrative body of the medical insurance system. The Board of Education might in theory be assumed to be interested, but in practice its contact with higher and professional education is, in the main, indirect and chiefly through the University Grants Committee. Another Ministry concerned is the Colonial Office, for under its general direction and supervision are several

medical services—in the West Indies and in East and West Africa, for example, it has, moreover, certain responsibilities towards the Dominions, for the Colonial Secretary is also the parliamentary head of the Dominions Office. We are very glad to know that the present Colonial Secretary recognizes this responsibility, and that he has discussed the matter with Sir Thomas Horder and evinced great sympathy and interest. Lastly we may mention the India Office, which also has an interest, because study leave is now granted to officers of the Indian Medical Service.

As has been said it is not to be expected that the new committee will have an easy passage, but before it assembles in October under the chairmanship of Mr Neville Chamberlain its members will have had the chance of digesting the Athlone report, and will doubtless have before them a sketch of the history of the movement, which will furnish sailing directions indicating rocks and shoals to be avoided. One of the first points to be decided will be whether to seek to adapt to the purpose of post graduate medical education an existing school, or whether to follow the example of the London School of Hygiene and Tropical Medicine and strike out for an entirely new institution. If a suitable existing school could be found a great deal of time and perhaps money would be saved, but emphasis must be put on the word suitable, no hospital or school on a cramped site, with small and perhaps makeshift laboratories, will serve.

We do not like to be too sanguine but certainly at the present moment there seems to be a better assured prospect of something definite being achieved than has been visible hitherto. The reference recently made by His Majesty the King to the need which all recognize, the personal effort put forward by the Minister of Health in assuming the chairmanship of an *ad hoc* committee, and the sympathetic interest shown by at least one of his colleagues in the Cabinet cannot but serve to give considerable momentum to the movement.

THE ANTITUBERCULOSIS CAMPAIGN IN GREAT BRITAIN

At the eleventh annual conference of the National Association for the Prevention of Tuberculosis on July 6th, an account of which appeared in our issue of July 11th (p 73), the value of the antituberculosis campaign in Russia and the United States was emphasized by the representatives of those countries. It may, therefore, be of interest to recall that in the *Edinburgh Medical Journal* for September, 1924, Sir Robert Philip published an address delivered by him to the fourth conference of the International Union against Tuberculosis at Liège in the previous August, in which he dealt fully with the effects of the antituberculosis campaign on the diminution of the mortality, with especial reference to Scotland. In Great Britain this campaign started as a small voluntary movement less than forty years ago, and was at first subjected to considerable criticism and opposition, but owing largely to the patient work of Sir Robert Philip, who has been elected President of the British Medical Association for 1927, these obstacles were gradually overcome. The opening of the Edinburgh Tuberculosis Dispensary in 1887 was followed, eleven years later, by the publication of the Edinburgh antituberculosis scheme (*BRITISH MEDICAL JOURNAL*, July 23rd, 1898, p 217), which included the co-ordination of such dispensaries, sanatoriums for early cases, hospitals for later cases, and working colonies. Royal Commissions inquired into the effect on human health of food derived from tuberculous animals (1890), the best administrative procedure to control the

risk of such infection (1896), and the relation between human and animal tuberculosis (1908). The legislative enactments with regard to tuberculosis embodied in the National Health Insurance Act of 1911 and the recommendation of the departmental committee formed to interpret the provisions of this Act that a co-ordinated tuberculosis scheme for the whole country should be adopted, provided the basis of the present system in Great Britain. Notification of pulmonary tuberculosis was made compulsory in 1912, and this was extended in 1914 to include all other forms of tuberculosis. The tabulated statistics for Scotland from 1871 to 1921, which form part of Sir Robert Philip's address, illustrate the practical results which have followed this campaign against tuberculosis. Throughout this period there was a steady fall in the tuberculosis death rate for Scotland, but the percentage reduction of mortality was remarkably pronounced in the later years: this was also the case in the corresponding figures for England and the United States. The tables show that while the general death rate in Scotland from all diseases was reduced by less than one-half during the fifty years 1871 to 1921, the total tuberculosis death rate and the rate for pulmonary tuberculosis diminished by more than two-thirds. Thus, for example, during the period 1911-21, whereas the death rate from all diseases decreased by 10 per cent, the total tuberculosis death rate showed a drop of 31 per cent, and the rate for pulmonary tuberculosis fell to the extent of 27 per cent. Again, in 1871 the total tuberculosis mortality in Scotland was 16.8 per cent of the general mortality, whilst in 1921 it was only 9 per cent; this reduction in mortality was conspicuously apparent in the age groups below 25, indicating the successful preservation of the lives of children, adolescents, and young adults. These gains cannot be attributed solely to improvement in sanitary conditions, since the statistics show that a greater influence has been exerted on tuberculosis than on other forms of disease. The suggestion that this improvement is to be attributed to progressive immunization of the population against tuberculosis is rejected on the ground that there is no evidence that the older civilizations presented any degree of uniformity in the diminution of the tuberculosis death rate; this rate remained high in many of the older nations where no active antituberculosis work is in progress. Again, presumption of some difference in racial susceptibility cannot, it is held, be seriously pressed as explanatory of this fall in the death rate in view of the universality of the disease throughout the civilized world, and the heavy toll that has been exacted by it from all nations throughout the ages. Sir Robert Philip therefore concludes that the interposition of some added influence must be postulated and there seems to be no alternative to the view that this influence is the campaign against tuberculosis.

THE DANGERS OF SANOCRYSIN TREATMENT

THE possibility of the occurrence of dangerous reactions during the course of sanocrysin treatment has received from the first the most careful attention of Professor Moellgaard, who dealt with the question of shock production at some length in his account of the theoretical basis of this treatment published in our issue of April 4th, 1925 (p. 643). Professor K. Friber, who has been associated with Professor Moellgaard's investigations, referred to these dangers in an address he delivered recently to the National Association for the Prevention of Tuberculosis (July 11th, 1925, p. 73). He has been conducting an extensive trial of sanocrysin at the University Hospital of Copenhagen, and in the *Ugeskrift for Læger* (April 16th, 1925) has made some observations which do not altogether tally with those recorded by Secher and Wurtzen in Moellgaard's book

on sanocrysin. Friber's first and most important point is that the danger of shock is particularly great if an injection is repeated before the febrile reaction provoked by a previous injection has completely passed off. He has found that a protracted febrile reaction may follow the first injection of even a small dose (0.5 gram), but may not occur directly after that or the second injection. From two to four days may elapse before the rise of temperature begins, and this interval at least must, therefore, be allowed before repeating the injection. Sanocrysin shock, I think, is most likely to occur in patients who are already febrile, and in such cases the initial dose should be small. Besides the danger of shock, early injections at too frequent intervals may cause hyperpyrexia, the case ending finally with signs quite distinct from those of shock. Albuminuria also seems to depend largely on the frequency with which the injections are repeated, for it is most severe and protracted when there is an interval of only four days between the injections; albuminuria is much less common when the interval is six days. Friber disagrees also with the opinions as to the connexion between albuminuria and shock expressed in Moellgaard's book, according to which the first sign of shock is albuminuria, the next manifestations of myocarditis, and the final sign a fall of temperature. The appearance of albuminuria is, therefore, supposed to be a signal for the immediate administration of serum. Later, however, does not accept this view, having found that the first signs of shock are a fall of temperature and manifestations of heart failure—notably tachycardia. Albuminuria may, indeed, appear with the onset of shock, but it may be completely absent or develop at a later stage. It is a very common sequel to sanocrysin treatment, and is observed quite independently of shock. When genuine signs of shock appear intravenous injections of serum are definitely indicated, and Friber thinks it probable that prophylactic injections of serum can avert or diminish renal disease in the early stages of treatment. But the advice given some time ago—that serum injections should be continued so long as albuminuria persists—is in his view not only useless, but even harmful, since such treatment is apt to make albuminuria worse or more prolonged. In the light of these observations Friber has found treatment with sanocrysin much simplified. The nurse must primarily watch for signs of collapse, such as general malaise, pallor, excessive perspiration, rapid pulse, and fall of temperature. The patient usually recovers from this shock when given serum by intravenous injection, oxygen with or without camphor—also by injection—and oxygen inhalation. The frequency of shock can be much reduced by increasing the intervals between the injections, a measure Friber prefers to reducing the dosage of each injection, even when the interval between the first two injections is only two days, thereafter a week should be allowed between the injections. Though the original large doses can still be given in febrile cases, patients who are already febrile at the commencement of treatment should be given small doses. Friber's closing statement is that he has become increasingly convinced of the beneficial action of sanocrysin in a certain proportion of cases of tuberculosis.

THE U.S. PHARMACOPOEIA

THE fact that preparations have begun for a new edition of the *British Pharmacopoeia* lends particular interest to the announcement that the tenth revision of the *United States Pharmacopoeia* has been completed, and that the new edition will become official in the United States at the beginning of next year. The duty of revision is entrusted to a corporate body with no direct Governmental affiliation, but when a new edition appears, every tenth year, it is

adopted by the United States Government as the official standard for medicines. Dr Robert A. Hitcher of New York read a paper on the new edition at the annual meeting of the American Medical Association last May,¹ from which it appears that the Committee of Revision is a composite body of clinicians, pharmacologists, chemists, and pharmacists. It appointed a subcommittee (on scope) of physicians to select the therapeutically active substances to be admitted. The pharmacists have been responsible for the selection of those articles which are included because they are pharmaceutical necessities, such as agents for testing chemicals, solvents, and menstruums, or substances for which standards must be provided but which the physician does not prescribe directly. The U.S. *Pharmacopoeia* of 1890 contained 994 titles, but the tenth revision will contain only 630 official crude drugs and preparations. It is, Dr Hitcher states, the duty of the clinician and the pharmacologist to select those therapeutic agents which are indispensable, and also to exclude those substances which are not indispensable. Of the articles official in the ninth revision 191 have been dropped, but 50 others have been added. Among the most important of those now admitted for the first time are acetylsalicylic acid, asphenamine, barbital, epinephrine, procaine hydrochloride, neo-asphenamine, quinidine sulphate, and mild and strong silver proteates. Congress has forbidden the manufacture of diacetylmorphine (or heroin) in the United States, and Dr Hitcher says that there is a consensus of opinion that it is fully replaced by morphine and codeine. Morphine, however, and stivamine, the alkaloidal bases, have been dropped, because these drugs are almost invariably used in the form of one or another of their salts. The Committee of Revision was much exercised in coming to a decision as to whether whisky and brandy should be admitted to the *Pharmacopoeia*. After long discussion they were omitted from the ninth revision, and after protracted consideration they have been admitted to the tenth. Their admission was, of course, almost unanimously favoured by those members of the committee on scope who are in general practice, and almost unanimously disfavoured by the laboratory workers. "The significance of this," Dr Hitcher rather cryptically says, "is left to individual consideration." He and Dr H. C. Wood, who took part in the discussion, laid stress on the importance of using the official names in prescriptions. "Manufacturers," Dr Wood said, "who sell their products under trade names are in no way bound to furnish products of standard purity; they modify their formulas at will, sometimes very considerably. These may have greater or lesser amounts of impurities, and whenever one orders a product by a proprietary name one has no guarantee of the quality of drugs or even of the kind of drugs that one's patient is going to receive, except the honesty of the manufacturer."

On the other hand," he continued, "when a drug is ordered by an official name, the druggist must dispense a drug that corresponds to the standards laid down in the *Pharmacopoeia*, or he is liable to prosecution by the Federal Government, and, in nearly every State in the Union, also by the State authorities."

ENDEMIC ROUND WORM INFESTATION

Dr Monckton Copeman has drawn timely attention in one of the Ministry of Health reports² to the intensive prevalence of the large human round-worm, *Ascaris lumbricoides*, in certain rural parts of England. The parasite was found to be endemic in a small hamlet in the

Beilhamsted district of Hertfordshire, and was responsible for a considerable amount of illness and even some deaths. It appears to have been present in this district for many years—at least sixty—and has been encouraged to remain there by the local method of using earth closets. The faecal contents of these closets are emptied regularly on to special plots and used as manure. Dr Copeman suggests that a second cause of the ascariid infestation may be traced to the presence of the morphologically identical worm in the local pigs, the manure from which is also used in the cottagers' gardens. He draws attention, however, to Professor R. T. Leiper's view that these two species are biologically distinct, and that the pig form will probably not infect man—at least in its adult state. This contention is confirmed by recent work in America and Japan. The question of biological strains of parasitic helminths is most interesting and important, because many human parasites are represented in the domestic animals by species morphologically identical. Some of these are undoubtedly transmissible to man, but in the case of the swine ascariid the available evidence points to the existence of two biologically distinct species which are not inter-transmissible. The pig form is extremely common in this country, and is responsible for much economic loss. Pig manure is extensively used for the production of food for human consumption, and yet it is only in certain areas that human infestations are found. The cause of the epidemic is accordingly almost certainly to be attributed to the use of untreated human excreta as manure. In addition to discussing the epidemiology of this subject, Dr Copeman gives a concise account of our present knowledge of the bionomics, pathology, and therapeutics of *Ascaris lumbricoides* in man.

SURSUM CORDA

In a small volume of seventy-five pages,¹ more than one-half of which are devoted to full page illustrations, Mr Grey Turner of Newcastle draws attention to an aspect of the surgical treatment of cancer which is apt to be overlooked. He addresses himself more especially to younger surgeons. Roughly speaking, it may be said that cancer is an inevitably fatal disease, and surgery cannot cure it, and in contemplating a series of brilliant excisions there is generally a tendency to ask doubtfully, "What about the after-histories of these cases?" This attitude is wrong, attention should be directed on what surgery can, not on what it cannot, do, and there is abundant evidence that in numbers of cases it can prolong life, relieve suffering, and practically extirpate the disease, so that the patient's life comes to a natural close through other causes. When one or other of these benefits is not obtained there is apt to be a depressing feeling of surgical failure, which is in fact unjustifiable, since the failure was inherent in the case and could not be avoided. The better course is to endeavour to sharpen our powers of diagnosis to enable a distinction to be made between cases in which one or other of the above-named benefits may be predicted, and those in which failure is certain. It is probable that, some day, a strictly scientific analysis of successful cases on the one hand and unsuccessful cases on the other will be made, and a comparison of the results should disclose valuable facts. Mr Grey Turner describes a series of cases in which distinct and often remarkable benefits resulted from the surgical treatment of cancer. Thus, among the excisions of the rectum by the perineal route cases are mentioned in which there was freedom from recurrence for 8, 9, 12, 13, 16, and 20 years. Out of 43 of the author's own cases who survived the operation of

² Ministry of Health Reports on Public Health and Medical Subjects No. 31. On Infestations of the Human Subject by the Nematode Worm *Ascaris lumbricoides*. By S. Monckton Copeman M.D. F.R.C.P. F.R.S. 1925 (Pp. 20. 6d net.)

¹ *Some Encouragements in Cancer Surgery*. By G. Grey Turner, F.R.C.S. Eng. Bristol J. Wright and Sons Ltd. 1925. (Roy. 8vo pp. 75. 4d figure. 7s. 6d. net.)

excision of the rectum for cancer and who were operated upon more than five years ago, 12 are known to be alive and well without recurrence, and 2 are known to have died without recurrence 16 and 13 years after operation. Down to the end of 1913 Mr. Gray Turner had operated on 114 cases of cancer of the breast, with 3 deaths immediately following. Of the remainder, 3 had to be discarded because there was no record of the microscopic examination. Of the 108 cases thus left available for the study of the after-history, 14 were ascertained to be alive and well 10 years or more after the date of operation, the respective periods being 11 years in two cases, 13 years in two, 14 years in three, 15 years in four, 16 years in two, and 18 years in one case. Other series are described in which the disease was situated in the colon, mouth, bladder, kidneys, genitals, oesophagus, or stomach. Two cases of sarcoma of bone are of particular interest. One was a chondrosarcoma surrounding the lower third of the shaft of the femur, and, judging from the figure, filling the medullary canal for several inches. The limb was amputated through the thigh, and the patient remains well without any suggestion of recurrence now twelve years after the operation. In the second case there was a central tumour of the upper end of the tibia, which was treated by enucleation on the supposition that it was a myeloma. It proved to be an osteosarcoma, and rapidly recurred. Amputation was performed, and some months afterwards the patient began to suffer from cough, shortness of breath, and blood-stained sputum. A diagnosis of tuberculosis was eliminated, and it was supposed that secondary deposits had occurred in the lung. However, the patient's health improved, and he is at present, seven years after the operation, in good health and free from all evidences of recurrence or dissemination.

THE DANGEROUS DRUGS ACT, 1925

A BILL to make minor amendments and some extensions of the Dangerous Drugs Acts of 1920 and 1923 was passed with amazing rapidity during the last days of the last session. Read a second time in the Lords on July 28th, it was introduced in the Commons on July 30th, read a second time on August 4th, and received the Royal assent on August 7th. As Lord Cecil of Chelwood explained in the House of Lords (as reported in our parliamentary notes on August 8th, p. 273), the need for it arose out of the opium conferences held in Geneva last winter, and anticipated the ratification of the convention dictated by the second conference. Down to June 17th last the Foreign Office was unaware that any ratifications had been deposited, and the convention will not come into force until ratified by ten of the signatory Powers. The Act brings coca leaves, and Indian hemp and resins obtained therefrom, under the same restrictions as raw opium. The inclusion of the latter was considered by the Hague Opium Conference in 1911-12, and the further study of its abuse advised before invoking national or international action. The requirement as to marking of packages of raw opium for export is repealed. Synthetic cocaine is included. The definition of "medicinal opium" is amended. Power is given to withdraw from the operation of the Acts any preparation of any drug named in Part III of the Act of 1920 which the Council of the League, as advised by the Health Committee, find cannot give rise to the drug habit and from which the ingredient dangerous drugs cannot be recovered. The Act is to come into force on such date as His Majesty may, by Order in Council, appoint, and different dates may be appointed for different provisions in relation to different countries. It will be seen that the amendments made in the principal Act (1920) are, for the most part, comparatively unimportant. The most serious

is probably that in Section 5, which provides for the removal from the operation of the Act of certain preparations, although containing dangerous drugs. It appears that the French and Belgian delegates at the conference also urged that chemists should be allowed in urgent cases to dispense "tincture of opium, Sydenham's Laudanum, and Dover's powder in doses not containing more than 25 centigrams of official opium." This was opposed by the British delegation as weakening the Hague Convention and enabling an addict to go from one chemist's shop to another, and so obtain large quantities of the drugs. It was nevertheless carried and included in the convention.

A HEALTH BULLETIN

THE Public Health Commission of the Government of Victoria has this year begun the issue of a quarterly bulletin of health. The first number begins usefully with a brief statement of some of the main provisions of the Victorian Health Act of 1919, under which the Commission is constituted and operates. The population of the State is 1,641,852, and its area 87,884 square miles. The Minister of Health is a medical man, and the Health Commission under him consists of seven members, of whom three are medical. The powers of the Commission are those usually appertaining to a central health authority. Its headquarters are in Melbourne. Local administration is in the hands of municipal councils, with such medical and other officers as are necessary. The State is divided into six health areas, whose boundaries may be altered from time to time. Each area has a whole-time district health officer. Local officers are removable, but appointments require the approval of the Commission. The duties of medical officers of health and sanitary inspectors are generally similar to those at home. The former are not required to possess a diploma in public health, which would no doubt be an impracticable condition at present. Sanitary inspectors must possess a certificate of competency after examination by the Commission, or a certificate of the Royal Sanitary Institute or other equivalent and approved authority, or have five years' experience. The bulletin contains also a series of articles on current health questions: the lessening of diphtheria prevalence, the Schick test and immunization, sanatoriums, the Spallinger treatment, anthrax, acute anterior poliomyelitis, and whooping-cough. Then follows a quarterly statistical tabulation of six of the notifiable diseases. The diseases notifiable, though not tabulated, include ankylostomiasis, anthrax, bacillary and amoebic dysentery, hydraditis, leprosy, malaria, and tetanus. Tables are given also of the distribution and age incidence of venereal diseases, whilst some small space is devoted to a note on the prevalence of infectious diseases in foreign countries. The Health Commission of Victoria is to be congratulated on its new publication. It will be of value, not only to the public health service, but also to the medical profession of the State and to the general public of Victoria.

THE HALF YEARLY INDEXES

THE usual half-yearly indexes to the JOURNAL and to the SUPPLEMENT and EPITOME have been published, they will, however, not be issued with all copies of the JOURNAL, but only to those readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Financial Secretary and Business Manager, British Medical Association, British Medical Association House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this desire.

VACCINATION AND TETANUS.

BY

JOHN C. McVAIL, M.D., LL.D.

AMERICAN medical periodicals reaching this country have very occasionally contained references to the occurrence of tetanus after vaccination. These references have always been puzzling to readers on this side of the Atlantic. Dr. F. D. Acland, in reporting on the sequelae of vaccination to the Royal Commission, made mention of tetanus,¹ and in an article by him entitled "Vaccination in 1914" published in Allbutt and Rolleston's *System of Medicine*, while pointing out that tetanus may follow an accidental infection of any wound, he stated that as a complication of vaccination it was of the utmost rarity, and that he was acquainted with only one case in more than five million consecutive vaccinations in this country. Even in that case there was no evidence that the tetanus was unvaccinated.

Much light is now thrown on the possibility of the occurrence of post-vaccinal tetanus in America, in an article by Dr. Charles Armstrong, of the United States Public Health Service, in the *Weekly Public Health Report* of that service dated June 26th, 1925.² The article is entitled "Tetanus following use of bunion pads as vaccination dressing." It states that eleven cases of post-vaccinal tetanus which followed the use of bunion pads as a dressing have been investigated.

The eleven cases were distributed over seven States—two in 1921, five in 1924, and four (down to May 20th) in 1925. Of the eleven cases nine proved fatal. Bunion pads of the same varieties and from the same sources as those used in the cases which developed tetanus were collected and examined. In addition, 186 similar pads were purchased in Washington, D.C., and examined. In about 25 per cent of these pads the tetanus organism was found. "The criterion of infection of the pads was the development, on glucose broth or meat mash media, of an organism morphologically like tetanus, which developed a toxin lethal for mice and neutralizable with tetanus antitoxin." Six medical practitioners in whose practice seven of the above mentioned cases of post-vaccinal tetanus occurred estimated that they had vaccinated about 700 persons on whom bunion pads were used as a dressing in 1924-25 whilst the cases of tetanus were developing. If 25 per cent of these pads were contaminated by tetanus, then about 4 per cent of the cases in which the risk was run developed the disease. Of the total eleven cases, nine were primary vaccinations. Whether the other two were primary is not known. In all the eleven the cross patch or scarification method of insertion was employed.

As regards the vaccine virus used, the report states that inquiries were made. The product of three different manufacturers had been used, in two cases, five cases, and three or four cases respectively. For only one case could the exact lot of virus be definitely ascertained. "Bulk samples of this lot were carefully retested by different workers using various methods, but no tetanus could be demonstrated." In other instances it was possible to determine that the virus must have been from one of several lots, but similar sampling and testing demonstrated no tetanus. Also among some 25,000 vaccinations in 1924-25, in the localities where the seven tetanus cases specially dealt with had occurred, no definite case of tetanus developed, though in one instance of a severe leg vaccination antitoxin was given on account of pain and stiffness in the neck, and prompt recovery was

regarded as indicating that the ailment was probably not tetanus. Notes are given of each of the eleven cases, and in several of them it is clear that the vaccination had not followed a normal course, but had been followed by an open discharging sore, which might be infected by the tetanus organism if present. The ages of the cases ranged from 6 to 30 years, nine were males and two were females. In nine cases the bunion pad was applied at the time of vaccination, and in two on the fourth day afterwards. The interval between vaccination and the onset of tetanus was 12, 15, 16, 19, 20, 20, 23, 24, and 28 days respectively in nine cases. In two the interval was uncertain. One case was vaccinated on the thigh, all others on the arm. Dr. Armstrong's conclusion is "The facts revealed by this investigation clearly indicate that the use of bunion pads as vaccination dressings should be strongly advised against."

Concerning bunion pads as a vaccination dressing in this country I have asked a London public vaccinator of the highest standing and long experience. He tells me that he has never seen or heard of such a dressing. But it happens that in 1902³ the *Lancet* published a report of singular interest in its bearing on this question. Drs. William Findlay and J. W. Findlay of Glasgow there gave a full account of a case of post-vaccinal tetanus in their practice. A vaccination was done midway between the knee and the ankle of a young woman, who preferred that site to the arm in order to avoid interference with her work, and "a large adhesive thick felt or bunion plaster was then applied round the vaccination mark and was kept in position by a strip of adhesive plaster, the object being to prevent any contact of stocking or clothes with the wound on the way from the surgery to her home until it was quite dry." The vaccination had been done with calf lymph, and several others had been vaccinated from the same tube, with no subsequent tetanus. In a careful study of the case—the woman recovered under treatment—the authors suggest the patient's own skin as the source of infection, the long trailing dress might have swept up dirt from the earth. They regret that the vaccination was covered up at the beginning and the dressing kept on through misapprehension. It is not surprising that at the date they did not discuss the possibility of the bunion pad being responsible. They found reference in medical literature to ten other cases of post-vaccinal tetanus. Six of seven of them were in America and two in the West Indies, but they had not access to the journals in which these were reported.

Dr. Armstrong's article indicates unequivocally the bunion pad and not the vaccine as responsible for the tetanus. The remarkable coincidence of the use of a bunion plaster in what seems perhaps the only case reported in this country since Dr. Acland wrote is of manifest significance, but, remote though the chance appears of the relevance of the important American discovery to conditions here, it suggests that the matter should, without loss of time, be the subject of investigation in two directions: one as to whether in fact the tetanus organism can be found in bunion or corn plasters or other adhesive plasters on sale here, the other as to whether such plasters are used in connexion with vaccination. The Ministry of Health would naturally be the body to make such investigation. It was the Local Government Board and the Ministry which, during the war,⁴ established the fact that imported shaving brushes were in some cases infected with anthrax, the administrative result being that orders were subsequently issued prohibiting further importation, while every endeavour was made to trace brushes belonging to consignments known to be infected, and to secure the destruction of brushes already on sale. A circular issued in 1921 dealt with the disinfection of hair used for the manufacture of shaving brushes in this country. If it were found that any kind of corn or other plasters carry the tetanus organism, then independently of vaccination, such plasters should be prohibited.

⁵ Report by Francis J. H. Coulter, M.D., New Series (L.G.B.) No. 112, 1917.

THE GENEVA OPIUM CONFERENCE

A REPORT signed by Sir Malcolm Delevingne of the Home Office has been presented to Parliament by the Secretary of State for Foreign Affairs, giving, in account, from the British delegation's point of view, of the two opium conferences held at Geneva November, 1923, to February, 1925.

The report recites the provisions of the Hague Convention of 1912, and describes the work done by the Opium Advisory Committee of the League of Nations since 1920 and the efforts of a preparatory committee to prepare programmes for the two conferences which the Council of the League, at the suggestion of the Assembly, resolved to convene. Readers of the *BRITISH MEDICAL JOURNAL* have been kept informed of the proceedings and results of these conferences, and the difficulties they encountered which led to the withdrawal of the United States delegation. It will be remembered that "the American principles" were—

'1 If the purpose of the Hague Opium Convention is to be achieved according to its spirit and true intent it must be recognized that the use of opium products for other than medicinal and scientific purposes is an abuse and not legitimate

'2 In order to prevent the abuse of these drugs it is necessary to exercise the control of the production of raw opium in such a manner that there will be no surplus available for non medicinal and non scientific purposes

Now the Advisory Committee on Traffic in Opium accepted and recommended to the League of Nations the proposals of the United States "as embodying the general principles by which the Governments should be guided in dealing with the question of the abuse of dangerous drugs and on which, in fact, the International Convention of 1912 is based." This acceptance and recommendation were subject to a reservation in regard to the temporary legitimization of "prepared" opium. The committee further "expressed the belief that all the Governments concerned will be desirous of co-operating with the United States Government in giving the fullest possible effect to the convention." The representative of the Government of India, however, made a further reservation to the effect that the eating of raw opium, as practised in India, is not to be regarded as illegitimate under the convention.

The fourth Assembly of the League, when considering the report of the Advisory Committee, requested the Council "as a means of giving effect to the principles submitted by the representatives of the United States of America, and to the policy which the League, on the recommendation of the Advisory Committee, has adopted," to invite the Governments concerned to send representatives to a conference for this purpose.

The report then describes the prolonged and controversial proceedings of the two conferences—the first dealing with restriction of the production and distribution of "prepared," the second with the regulation of the drugs. The work of the two conferences could not be kept separate as it was part of the American case that the use of smoking opium should be brought to an end within a defined period, and implied a limitation of the production of opium for that purpose. The amalgamation of the two conferences was opposed by Great Britain, although it was recognized that the findings of the first might have a bearing on the work of the second. A joint committee of the two conferences failed to remove the deadlock, and this "negative result" led to the final withdrawal of the United States delegation. This was followed by the withdrawal of China also. The protocol resulting from the labours of the first conference, while purporting to strengthen and supplement the provisions of Chapter II of the Hague Convention, which pledged the contracting Powers to the gradual and effective suppression of opium smoking, included no provisions for the direct limitation of the production of and commerce in "prepared opium." The British delegation "regretted it had been unable to go further" and the results "greatly disappointed many persons interested in the Far East," the Missionary Council even asserting that "the British Government is con-

senting to what would be a backward step." The final and indefinite decision of the first conference was to undertake "to suppress the consumption of prepared opium within the period of fifteen years from the date, as determined by a League of Nations commission, when the smuggling of opium from the producing countries ceases to be a serious obstacle to the enforcement of restrictive measures."

The second conference, in which forty-one States participated, held thirty-eight sittings, of which nine were occupied with procedure and twelve with the difficulties raised by the American proposals. On a vote being taken on the question of dealing with the limitation of the production of opium to medicinal and scientific purposes, out of the 36 delegates present 26 including Canada, voted for the American "principle," 9, including Britain and Australia, abstained from voting, while the Indian delegate alone voted against. In regard to this, however "nothing in the end did happen." The scheme finally adopted for limiting the manufacture of the drugs was, the report asserts, "a much more modest one than the original British scheme proposed," and "falls very far short of attaining the object proposed to the conference of limiting the manufacture of morphine, heroin, and cocaine to the amounts required for medicinal and scientific purposes." The conference "failed to accomplish anything in regard to that part of the agenda which referred to the limitation of the production of opium for export," and this in spite of the British delegate "urging the conference not to lose the ground that had been gained," seeing that "the Hague Convention already requires the States to exert effective laws on the subject." The inclusion of cocaine and cannabis indica is a poor compensation for this regrettable omission. Lastly, the report states that the British estimate of the requirement per head of raw opium for medicinal and scientific purposes is very much less than that of 450 milligrams as determined by the Health Committee of the League of Nations.

On the whole, while recognizing that some minor amendment and extensions have been made upon the Hague Convention of 1912, it is not, we fear, possible to share the view that "a very great advance" upon that important international treaty has been effected. The failure to give effect to the American principles, behind which so large a volume of support had been collected, was lamentable, and should it lead to the lack of the co-operation of the United States in future effort would be disastrous.

While Professor Perrot, one of the French delegates writing in the *Revue Scientifique* of July 11th, finds grounds for modified satisfaction in the achievements of the conferences, Sir William Collins, who was a British delegate at the three international opium conferences at the Hague, writing in the *Contemporary Review* for August, takes a less sanguine view of the situation. A further article by Mr. C. F. Andrews in the same publication severely criticizes the position taken up by the Indian representative, and attributes to the obstructive tactics of the Indian Government some of the unfortunate failures which characterized the Geneva conferences.

NATIONAL VETERINARY MEDICAL ASSOCIATION

The annual congress of the National Veterinary Medical Association is being held this week in Cambridge under the chairmanship of Mr. ARTHUR GORTON, F.R.C.V.S., President of the Association, and chief veterinary officer for the city of Edinburgh. A considerable number of papers have been read which are of general medical interest.

Rations for Normal Animals

Professor T. B. WOOD, F.R.S., said that until towards the end of the eighteenth century, when the growing of root crops became general, farm animals were underfed throughout winter on straw and hay, with the occasional use of a little corn. Fresh meat and mill were practically unobtainable in winter, and the use of roots was the first step towards providing a supply. This was followed in about fifty years by the introduction of concentrated feeding stuffs, such as oil cake, but these were used more or less empirically and often extravagantly. It was not

Miscellaneous No. 8 (1925) Cmd. 2461 obtainable at H.M. Stationery Office price 1s.
BRITISH MEDICAL JOURNAL, December 6th 1924, January 10th 1925, January 31st 1925, February 14th 1925, February 28th 1925, March 28th 1925.

until quite recent years that scientific physiological investigations on living animals were begun to estimate the exact requirements of animals for the production of milk, beef, and work. Great strides had been made in "milk rationing," and had been attended by much improvement in the yield of milk. Much cows required just over half a pound of digestible protein for every gallon of milk produced, but in practice most cows were underfed in this respect and so did not give a maximum supply. Growing animals required, in addition to a definite amount of protein, a certain amount of ash constituents—more especially lime and phosphoric acid—and they, too, were generally below what was necessary. On the other hand, stock for fattening needed a diet very rich in carbohydrates, but were much more frequently given the protein which should be used for milk production and growth. Thus, Professor Wood said, was a dangerous as well as an uneconomical process. A diet, he observed, consisted of two parts: (1) the maintenance ration, which was definitely related to the live weight of the animal and provided for the normal vital functions, and (2) the productive ration, which was proportional to the result the feeder desired to produce—milk, meat, growth, or work. To provide these two rations successfully it was necessary to have a knowledge of the chemical composition of the various feeding stuffs, the practical application of this information could easily be ascertained from tables.

The Tuberculosis Order

Lieut.-Colonel J W BRITTEBAK, F R C V S, said that tuberculosis in animals—especially in milk cattle—had a twofold interest: it not only provided an undoubted source of infection for human beings, especially children, but it caused enormous direct and indirect losses in the animals themselves. Concerted action should be taken for its reduction and eradication. The reintroduction of the Tuberculosis Order of 1914 had become necessary, and it should be strictly applied. A definite policy with regard to the sanitation of cow-houses was a first consideration, for without it little could be done. He advocated the employment, by the administrative bodies concerned, of trained veterinary clinicians, and deprecated resort to the police, who could not be used without causing considerable resentment. He was not in favour of a non-contributory scheme for compensation, believing that it would tend to penalize the up-to-date scientific farmer at the expense of the negligent. Clinical examination of animals would be of much more value than the use of tuberculin in diagnosis, and he gave figures to show the successful application of such a system in Manchester in reducing tuberculosis in milk.

Recent Regulations for Food Inspection

Mr J McALLAN, M R C V S, expressed the opinion that Great Britain, which had been a pioneer in so many branches of hygiene, had lagged behind in the inspection of meat and food, only within the last year had any considerable advance been made. During that period some half dozen Regulations and Orders had come into operation. They were framed to secure more adequate inspection of animals slaughtered for food, and to ensure improvements in the handling and transport of food generally. One important consequence was the recognition that the veterinarian was the proper person to pass judgement on animal pathology and diseases. The Public Health (Meat) Regulations, which became operative on April 1st, 1925, while dealing to a certain extent with the actual slaughtering of animals and inspection of carcasses, treated more fully the problem of handling, transport, and distribution of meat to the consumer. The Regulations, if enforced, would do much to improve slaughterhouse control in England. The Rural District Councils (Slaughterhouses) Order, which came into operation at the beginning of this year, applied to the whole country the provisions of the Public Health Acts as to slaughterhouses already in force in urban areas. The Public Health (Meat) Regulations (Scotland), which came into force on August 1st, 1924, were more far-reaching than the corresponding English ones. They provided a uniform system and a uniform

standard of meat inspection throughout Scotland. The Public Health (Imported Food) Regulations (England) and the Public Health (Overseas Meat) Regulations (Scotland) both came into force on June 1st, 1925. They provided for the inspection of all meat landed in this country and insisted on a very necessary control over imported meat and on a uniform system of inspection. The Public Health (Unsound Food) Regulations (Scotland) became operative on the same date, they made it an offence to import for sale any article of food examined abroad by a competent authority and found unfit for human consumption. Other regulations dealing with the use of preservatives, etc., in food were in preparation and would soon come into force. This series of Orders would complete a series which, although far from attaining perfection, would do much to raise the standard of food inspection and control throughout the country.

Some Recent Advances in Veterinary Helminthology

Dr T W M CAMERON, M R C V S, said that the losses in stock in this country due to parasitic worms probably amounted to millions of pounds annually. Dr Cameron considered that certain broad general principles underlay the eradication and treatment of helminthic infections. Before an exact knowledge of prevention and treatment could be obtained it was necessary to have an exact knowledge of the morphology of each species. Two closely allied species might have very different life-cycles, and might react in different degrees to various anthelmintics. Identification must be considered an index to the available information on the life-history and susceptibilities of the parasite found. Once identified, from the adult or its ova, the next step was to study the life-history, and from it find how to adopt the measures necessary to prevent infection. It was necessary at this stage to remove the adult from the animal body in order to prevent the further spread of the infection, and the value of critically tested anthelmintics must be considered. It was important to regard an anthelmintic as a preventive rather than a curative agent. Thus, for example, the dog might harbour tapeworms without showing any symptoms, but such an animal might spread the ova throughout large areas, and so infect man and animals with the various cystic stages. Some of the important stock diseases due to parasites in Britain were then considered in detail, and in conclusion stress was laid on the value of the services of zoologists in the laboratory rather than the veterinary surgeon, for a breadth of view not otherwise obtainable was thus gained. This principle had been adopted to a considerable extent in the American medical schools, and was in operation in the Institute of Agricultural Parasitology in this country.

Victoria.

Puerperal Morbidity and Mortality

In June, 1924, the Victorian Branch of the British Medical Association appointed a committee to inquire into the conditions of midwifery work in the State. The committee elected Dr J W Dunbar Hooper to be its chairman, and subsequently appointed Dr J Ramsay Webb to be vice-chairman. It met weekly on twenty-nine occasions, and one of its first steps was to issue a paper of questions to all registered medical practitioners in Victoria, the number of replies received reached the gratifying total of 234. The committee was also assisted by a number of medical and some other witnesses, including the Government statisticians and the matrons of several hospitals. The report, which was presented at the end of March last, has now been published in a pamphlet, in it the answers mentioned above are analysed, and certain recommendations made by the honorary medical staff of the Prince Alfred Hospital are set out in full.

The report opens with certain tables giving maternal and neonatal mortalities during the last twenty-five years. Both sets of figures compare unfavourably with those of Great Britain, and indeed most other countries. The committee is of opinion that, as in other countries, the actual figures are even higher than these statistics indicate, and that this represents a serious state of affairs, clearly calling for urgent reforms in the maternity service.

Its consideration of the way in which the service may be improved led the committee to express the view that many of the deaths might be avoided by better management.

The importance of routine ante-natal work which by the early detection of such conditions as albuminuria, puerperal infection and malpresentation may avoid many disasters is emphasized. It is pointed out that other problems such as toxæmic pregnancy and puerperal infection require further research for their elucidation and later in the report research grant are recommended with this object in view.

The obstetric service is then criticized under a crop of headings.

Government Activities

It is recommended that the Government should spend money on the establishment of ante-natal clinics, welfare centres and more extensive hospital accommodation. In this connection the nationalization of the service is considered, but dismissed as a retrograde step. The notification of puerperal fever is criticized, some administration difficulties discussed and suggestions are made for increasing the efficiency of notification.

The Medical Practitioner

It is urged that more efficient training should be provided for students and nurses. It is noted that in Victoria the medical practitioner attends at least seven eighths of all the confinements—that is 87.5 per cent—as compared with about 40 per cent in England and Wales. The committee considers that the university curriculum does not afford adequate training of the practitioner, a complaint which is not uncommon in respect to many other curricula in older communities. It will be a surprise to all accustomed to British methods to learn that the general hospitals under take no obstetric service. It would seem as the committee points out, that this aspect of the subject must be considered along with the admittedly unsatisfactory state of the obstetric service in the community. Again in considering the practitioner, stress is laid on the need of better training particularly as to more extended practical experience before qualification. The appointment of a professor of obstetrics in Melbourne is urged and an extension of the extern midwifery service recommended. The present teaching in Melbourne is adversely criticized, the difficulty of increasing the time allotted to the subject in a curriculum already overcrowded is recognized, but the members of the committee express the unanimous opinion that more time must be found for the study of obstetrics.

The Midwife

In dealing with the work of the midwives the need of longer study (eighteen months is mentioned) and a higher examination standard are emphasized. A special course in ante-natal work is suggested in order to cope with the difficulties of the more sparsely populated areas and to supplement the ante-natal work of the medical practitioners. The opinion is expressed that puerperal fever should not be delivered by midwives or at any rate not unless they have been under the ante-natal care of a practitioner.

The work of the Irish nurse (who are general nurses qualified in midwifery) receives commendation.

Ambulances Transport

The remaining points are briefly dealt with and have regard to the problems of ambulances and transport especially in relation to the country districts.

The need of more money for more adequate hospital accommodation, and for the gradual education of the general public to the fuller appreciation of the requirements of a really good obstetric service and all it means to the community at large, are then stressed.

Though the dominant factor of sepsis is less directly dealt with than is common in reports on maternal mortality, it is implied and involved in the consideration given to the problems of the accidents, hæmorrhages, and complications of labour.

The report is of real value and will no doubt receive the careful consideration of the Special Committee on Puerperal Morbidity and Mortality recently appointed by the Council of the British Medical Association. It illustrates that we have here to deal with a world problem, for, as in all such reports and from all available countries, the essentials are reiterated, and, *mutatis mutandis*, they begin with the call for properly organized research and amended education to radiate through the whole gamut of the administrative machinery, even unto that ultimate out in the personnel—so difficult to materialize—the perfect “home help.”

The essential foundation upon which all successful schemes must rest has not been forgotten, and the view that an enlightened public opinion will remove much of the existing administrative difficulty and, in turn, exact a high standard of work from all concerned, is thoroughly sound.

Ireland.

MINISTER REGISTRATION IN THE FREE STATE

SOME astonishment not unmixed with apprehension has been caused in Dublin by a statement made last week on behalf of the Irish Free State Government to the effect that it had decided to set up a separate medical register for the State. The matter has been under discussion for about two years, and last February the Legislature of the Free State enacted that pre-existing arrangements should continue for another year. Mr Cosgrave, President of the Executive Council of the Free State, is reported to have said last week, “That an important profession within the State should have its centre of gravity and disciplinary headquarters in the capital of another country is felt to be so incompatible with our constitutional status that we must be prepared to face whatever minor and temporary disadvantages may accrue from the cessation of that arrangement.” He added that the Executive Council of the Free State anticipated no serious reactions from the establishment of a self-contained and self-controlled medical authority in the State, and that the alternative arrangement to the present system was one for negotiation between the Irish Free State Government and the British Government. From a statement made in the *Irish Times* by the President of the Royal College of Surgeons in Ireland, Mr R. C. B. Munnell, it would appear that this is intended to mean negotiations to establish complete reciprocity, and the suggestion has been made that graduates of universities and diplomates of licensing bodies in the Free State should be entitled to have their names placed upon the Colonial List of the *Medical Register*. Mr Munnell did not consider this to be a practicable solution. He went on to say that some two years ago the Government of the Free State had invited representatives of the National University, Trinity College, the Royal Colleges of Physicians and Surgeons of Ireland, the Apothecaries' Hall, and the University Colleges of Cork and Galway to discuss the matter. These representatives held several meetings and came to the unanimous decision that the relation of the medical profession to the General Medical Council should not be altered. As they had been invited to explore every avenue they reported that the next best thing would be that the names might be inserted on the Colonial List of the *Medical Register*. This committee of representatives afterwards met the Minister for Local Government, the Minister's attitude was sympathetic and he assured the committee that everything would turn out satisfactorily. This assurance was subsequently renewed to a deputation from the Royal College of Surgeons in Ireland. The Government, however, afterwards raised the point that the committee contained no representatives of the rank and file of the medical profession, whereupon a new committee was constituted, as stated in our issue of April 18th, consisting of Senator Dr O'Sullivan, Dr T. Hennessy, F.D., Prof. A. F. Dixon, Sir James Craig, T.D., Mr Munnell, Dr Coffey, and Dr Magennis. This committee Mr Munnell states, was not summoned until August 13th, when Mr O'Higgins, Vice President of the Executive Council and Minister for Justice attended on behalf of the President of the Free State, Mr Cosgrave. Mr O'Higgins said “that it would be unthinkable to let things remain as they were as it would not be in conformity with the status and dignity of the Free State. It would never do to have a body of responsible men scattered through the land who would look to London as the controller of their actions. We must,” he continued, “have a separate register, and if not that, the Government might, as a last resort, allow you to go on the Colonial Register, but certainly you shall not stay on the General Register. I know that the profession will suffer, that is, in its schools it will lose students, but you must be satisfied to suffer something for the sake of the status and dignity of our country.” After some discussion Mr O'Higgins said, “Any way the decision is final, and I advise you not to waste your time in trying to alter it.” Mr O'Higgins shortly afterwards withdrew.

The position for the moment is confused and until the opinion of the medical profession in the Free State has

been fully ascertained we are not prepared to comment upon it further than to say that it seems to raise some questions of constitutional law. Existing rights, we think it may be assumed, will be saved, but the position of those who are now students of Irish medical schools or may enter them in the future is not clear. It is stated that the universities and licensing bodies of the Irish Free State give qualifications to about 150 persons a year, and that the State itself only absorbs about twenty. The Medical Act of 1886 is, however, elastic, it will be a question first for the General Medical Council and then for the Privy Council. The proposal of the Government is, we are informed, condemned by newspapers of all shades of opinion in the Free State. It is being criticized in a very adverse sense by medical teachers in Dublin.

England and Wales.

A YEAR WITH THE METROPOLITAN POLICE

THE Commissioner of Police of the Metropolis in his report for 1924, recently presented to Parliament (H.M. Stationery Office, 1s net), states that the men are proud of their calling and of the trust reposed in them, and speaks also in complimentary terms of the fifty women police. The area for which the metropolitan police force is responsible is 700 square miles, and the strength of the force is 19,356, including 842 officers in the Criminal Investigation Department. A policeman's lot, whether or not a happy one, can scarcely be described as a healthy one. Last year 1,457 police were injured in the execution of their duty, and 832 were otherwise accidentally injured. Although a picked body of men, the average daily number on the sick list or on sick leave was 718 during 1924, and in addition to 43 who died, 194 left the force through medical unfitness or ill health. The number of policemen admitted to London hospitals during the year was 756, and x-ray examinations were made in 237 cases. Crimes of violence in the metropolis show, on the whole, a decrease. There were 16 cases of murder of persons above 1 year of age and 12 cases of infanticide during 1924, as against 27 and 15 respectively during 1923, in three of the cases the murderer remained untraced. Cases under the Dangerous Drugs Act showed a striking decrease. In 1923 there were 103 such cases, and the number of persons proceeded against was 72, in 1924 the numbers were 26 and 19 respectively. The decrease is ascribed by the Commissioner to the deterrent effect of the heavy sentences, in some cases penal servitude, imposed frequently during 1923. The number of prostitutes charged with offences actually connected with prostitution was 1,072, of whom 823 were convicted, this is a large increase on the previous year but a decrease on the average of recent years. A slight increase (24 in a total of more than 30,000) is reported in the number of convictions for drunkenness. A seasonal curve is presented showing the remarkable variations in the number of these convictions, they were low during the first four months of the year, reached a high peak in May and another in June, and then remained fairly low, though not so low as in the earlier months until Christmas, they reached their highest point for the whole year in Christmas week. One cheering fact for the reformer is that the number of persons apprehended for drunkenness in proportion to the population is now only about one half the average for the pre-war decade 1905-14. The Commissioner notes a relatively large increase in the cases of drunkenness due to the drinking of methylated spirit which appears to be more popular among females than among males. The traffic conditions are reflected at many points in the police figures. Motor-car offences totalled 40,230 or 11,246 more than in the previous year. Traffic fatalities numbered 844, as against 668 in 1923, and 675 in 1922. The victims in 70 per cent of the cases were pedestrians. Horse drawn vehicles accounted for only 51 of the fatalities, and pedal bicycles for 42. Mechanically propelled vehicles were responsible for the remainder. The private motor car has an unfortunate pre-eminence in this respect, especially in the case of the fatalities which occur

at night, but the motor cycle is coming along at a rapid rate. Last year it killed 66 persons, an increase of nearly 70 per cent on its toll of victims in either of the two previous years.

HEALTH PROPAGANDA BY LOCAL AUTHORITIES

The London County Council has decided to make application to Parliament in the session of 1926 for authority to enable the council to undertake, and contribute towards the cost of, health propaganda work, and also to enable the metropolitan borough councils to undertake such work. The council had previously by resolution expressed the view that it was desirable for local authorities to take up propaganda work on the preventive side of public health. In the committee stage of the Public Health Bill, 1925, a new clause was proposed for the purpose of giving powers to public health authorities to undertake such work, the later part of this clause, however, which proposed that in London such powers should be conferred on the county and the borough councils, was ruled out of order presumably because the main object of the measure is to confer new health powers on authorities outside London.

KIDDERMINSTER HOSPITAL EXTENSION

In two previous issues, April 5th 1924 (p. 642), and March 14th, 1925 (p. 526), we referred to the scheme to increase the accommodation for children and out-patients in the Kidderminster and District General Hospital. The estimated cost of this extension was £25,000, and of this sum approximately £22,500 has now been raised. The commemorative stone of the new buildings was laid by Mrs. Stanley Baldwin on August 13th in the unavoidable absence of the Prime Minister. The new building, which will adjoin the present block, will contain in the basement a laundry, and on the ground floor an out-patient department comprising consulting rooms, examination rooms for men and women, dressing rooms, dental rooms, a dispensary, an operating theatre, and a large waiting hall. On the first floor there will be a new ward for forty children, with an open air balcony. Part of the old block will be converted into a nurses' dining room, an x-ray room, and servants' quarters, and over the present out-patients' department a new ward for women is to be built. The Kidderminster Hospital dates back to 1821, when a dispensary was established, in 1850 it was enlarged for the reception of in-patients. In 1870 an extensive reorganization was effected by Mr. Samuel Stretton, surgeon of the institution, his son, Mr. J. L. Stetton, now president of the hospital, is promoting the present extension scheme, and his grandson, Mr. J. W. Stretton, is surgeon to the hospital. The president is appealing for the remaining £2,500 required, and it is hoped that within the next twelve months the extensions may be opened, fully equipped, and entirely free from debt. It is believed that the cost per bed will work out at considerably less than the £400 which was the original estimate of the Voluntary Hospitals Commission.

VACCINATION IN L.C.C. TRAINING COLLEGES

Some time ago the London County Council, in revising the regulation dealing with the vaccination of officers, teachers, and employees under the direction of the Education Committee when small-pox occurred in their homes, or in institutions in which they were working, laid down a uniform instruction that the vaccination should be carried out forthwith, without reference to any stipulated period. At the last meeting of the council before the summer recess it was resolved to make a similar instruction in the case of students in training colleges. The resolution was as follows: "That in the event of a case of small-pox occurring in the home of a student attending a training college, such student must be vaccinated forthwith if he or she has not been vaccinated within the preceding seven years, otherwise the facts must be reported to the school medical officer, who will decide what course is to be pursued." It was also provided that in the event of a case of small-pox occurring in a training college, hostel, or approved lodgings, all students therein, who had not been vaccinated within seven years, must be vaccinated forthwith, or the facts reported as in the other instance.

Correspondence.

THE ADDITIONAL VOLUNTARY HOSPITAL
ACCOMMODATION REQUIRED

SIR,—In the report of the Voluntary Hospitals Commission¹ the public and the medical profession have to thank Lord Onslow and his colleagues for a document of real and permanent value. It is infused by a breadth of outlook and a grasp of constructive policy which cannot be without effect in the future of our hospitals. It should be read in its entirety by all who are interested in the subject, but it raises certain points to which I should like to direct the attention of your readers.

In the problem before the Commission—the adequacy of hospital accommodation—they were immediately faced by the question of what adequate accommodation means, and their analysis of the problem is as interesting as it is instructive. They do not, however, appear to have asked themselves why accommodation has become inadequate or for whom further accommodation is required. If they had done so they would have found that it is demanded, in my opinion quite properly, by a class who until recently would never have been regarded as suitable subjects for hospital treatment, a class which by no stretch of the imagination can be regarded as necessitous poor. The advance of medical science has resulted in the development of methods of treatment more and more expensive, and less and less adapted for application to isolated individuals. It is only by institutional methods that they can be applied at a reasonable cost, or indeed that they can be at all applicable for any but the rich.

The provision of medical treatment for this class has no proper claim upon charity, and the claim for a State grant might be based on broader grounds of public policy. But as to the wisdom of the grant proposed there can be no question at all, whilst the limitation to half the actual expenditure involved is probably wise in what is essentially a new venture on the part of the State. It is indeed a new venture of momentous consequence, for if I am not much mistaken it is the beginning of a State endowment of the hospitals, as institutions open to all those who need their services and not restricted by mistaken sentiment to one class. Such an endowment must bring with it an entirely altered relationship to the hospital not only of its patients, but of its medical staff and the wisdom and foresight of the British Medical Association in formulating a Hospital Policy to meet these changed conditions is amply vindicated.

The Commission has recognized in a very striking manner the great services rendered by the large voluntary hospitals, urging that they should be used more and more in a consultative capacity and "be reserved for cases requiring special diagnostic facilities or a high degree of technical skill." The Commission urges this in the interests of economy, of the patients themselves, and of the students for whose training these large hospitals are almost entirely responsible. At the same time it points out that for the student a wide range of clinical material must be furnished, and it deprecates the entire removal from his view of such cases as surgical tuberculosis, pointing out that the tendency at the present day to relegate these to the local authority is not without its dangers.

A Government document which recognizes the importance to the State of medical education, the value to the State of the supreme technical skill to be found concentrated in the large voluntary hospitals, and the responsibility of the State for seeing that there shall be room in these and other hospitals for all who need their assistance, marks an epoch in the history of our medical services. It is to be trusted that it marks the end of that narrow policy which would restrict the services of our great hospitals to the "sick

pool," whoever at the present day they may be, and which would prohibit the use of their funds in any form whatever for the education of those very students upon whom the whole service of the hospitals must in the end depend.

I trust, too, that this document will do nothing to ally the eyes of Government control. To one who has seen with anxious eyes the superbly equipped clinics of Switzerland, Paris, Holland, and Belgium, all established and maintained by the State, there is something a little ludicrous in the assertion that we alone of all nations cannot be trusted to manage our affairs with reasonable intelligence, and that the hand of our Government—which is, after all, ourselves—must wither at it touches. I for one should be only too happy to entrust the affairs of our hospitals to the Commission which has drawn up this report, feeling well assured that we should receive nothing but support, encouragement, and inspiration—I am, etc.,

H. S. SOUTAR,
Chairman Hospitals Committee
British Medical Association

August 17th

SIR,—Members of our profession, whether in general or hospital practice, and particularly members of the British Medical Association, will not fail to be impressed by the report of the Voluntary Hospitals Commission on Voluntary Hospital Accommodation in England and Wales, of which you published in account in the JOURNAL of August 15th (pp. 305 and 299). Five years ago we were told that the voluntary principle in hospital management was dead and that we must prepare to submit it in early date to the embraces of an all-compelling State scheme. The JOURNAL has had their little day. Their voices are now hushed by the compelling logic of events. The report shows that the voluntary hospitals are not only holding their own but that they are advancing in efficiency and security. Debt balances have been converted into surpluses and large sums have been spent on improvements, mainly in that need and productive field of better housing for the nurses. The fact that so much has been accomplished in a time of such financial stringency is eloquent testimony to the vitality of the voluntary principle.

So far little or nothing has been done to overtake the accumulated arrears of the ten years' war period in new construction of patients' accommodation. The business of the Commission was to determine the volume of these arrears, and to suggest how these might be most readily made up. The inquiry carried out by the Commission shows that on a conservative estimate there are to-day needed no fewer than 10,000 new beds in England and Wales, including London, or, to put it in terms of money, at the low rate of £400 per bed, there is needed a capital expenditure of four million pounds. It would appear that this is a minimum estimate after allowance has been made for increasing expenditure of the accommodation provided in Poor Law infirmaries and for closer association between cottage and city hospitals, so that relief may be given to the strain felt by city hospitals.

A call for four million pounds of new money from the beneficiaries of voluntary hospitals is scarcely practicable at the present time. Yet the demand must be met if the voluntary hospitals are to be maintained in that high position of efficiency which will alone justify the retention of their priceless heritage of independent management and freedom from cramping statutory control. The Commission recommends "a grant of 50 per cent of the cost up to a maximum of £200 per bed, subject, of course, to the remaining 50 per cent of the expenditure being raised or being available from existing building funds." The experience of the usage of the grant from the State through an intermediary body to tide over the emergency of 1920 proves that this timely grant did not in any wise supplant the independence of voluntary hospital management, and the proof of its benefit is seen to-day. The provision of an emergency building grant is calculated to stimulate benefactions in the same way. But even so it may not be possible to gather in the near future the required two millions of new money to meet the provision of the like amount by an Exchequer grant, supposing that this grant were conceded. It seems to me that there is another mode whereby the urgency of the situation might be met. During the reconstruction

¹ Voluntary Hospitals Commission. Report on Voluntary Hospital Accommodation in England and Wales. London: H.M. Stationery Office. Cmd. 285. Price 6d. An analysis of the report was published last week (p. 305).

This has been set out in a pamphlet *Policy Affecting Hospitals* issued recently by the British Medical Association. It can be obtained on application to the Business Manager at the Association's House, Tavistock Square, London, W.C.1.

period some of the most successful business and manufacturing projects have been secured by private enterprise operating with Government credits obtained through the provisions of the Trade Facilities Act. The application of similar methods to the raising of the new money required for hospital construction would appear to be a feasible proposition. The issue of "hospital bonds" under the Government guarantee of the Trade Facilities Act, and bearing interest, would enable many to lend who could not give. The terms of such loans would be more favourable to the hospitals than the customary bankers' overdraft, and the existence of the bonds would be a special inducement to local patriots to aim at their early extinction. Time is an essential factor if the voluntary hospitals are to be re-established in their full efficiency. Such a scheme would allow the favourable hour to be seized. Delay might bring about a settlement in a period politically unfavourable to voluntary hospitals.

Section 21 of the report deals with a proposal for the reconstitution of the Local Voluntary Hospital Committees, which are the peripheral nerves of the Commission. This section is one that calls for special attention by the executives of every Division and Branch of the Association. The Commission recognizes "that the representation of the hospitals and the medical profession should be increased." The recommendation is on the lines of the policy of the Association. It is urgently necessary that each Division and Branch of the Association should put that policy into force. In each Local Hospitals Committee of the Association should be formed, representative of all sections of the profession, so that there may be a vigorous and instructed local medical opinion ready to assist the Local Voluntary Hospital Committees in their reconstitution and in the responsible tasks that may be committed to them. In recent years energetic laymen have launched schemes for improving hospital facilities to which medical practitioners have had to take exception *after these have been launched*. If now, at this critical period, we fail to be in the field early and before plans have crystallized, our views and our experience may be lost by default—I am, etc.,

London W Aug 15th

N BISHOP HARRIS

SIR—The articles in the JOURNAL of August 15th on the report of the Voluntary Hospitals Commission will be read with much interest by all general practitioners, and especially by those working in cottage hospitals.

Section 10 of the report makes one a little fearful lest anything should be done to interfere with the growth and development of this part of our hospital service. Its extension during the last few years has been so remarkable that it is to be hoped that its evolution will be encouraged and allowed to proceed on natural lines. Nothing would be more disastrous than to stereotype these general practitioner hospitals, or to attempt, at present at any rate, to fix a standard for their work.

The section referred to repeats the complaint made in Sir Napier Bunnett's report for 1922, and mentioned in a leading article in the JOURNAL for July 21st, 1923, that too large a proportion of beds in cottage hospitals are unoccupied. I attempted to show in a letter published on August 18th of that year that this want of use is rather apparent than real and there is no doubt that in general an increase in the number of beds in a small hospital is followed by a higher percentage of occupation.

If 10,000 extra beds are to be provided it is important that the small hospitals should share in any grant that is made. Then share should, in fact, be considerable, for it is probable that many large hospitals, if they were relieved of all the cases that could be treated adequately by general practitioners in properly equipped institutions of their own, could deal with the cases left without the addition of any, or at any rate many, beds. Also a larger number of cottage hospital beds would enable many cases to be treated at an earlier stage and so prevent the necessity for that more special treatment that, for want of this timely attention, is afterwards required.

I am fully in agreement with the report that much might be done by co-operation between the staffs of the large and the small hospitals, but this requires much careful consideration and discussion by all concerned in order to obtain

the full benefit of the mutual service and to prevent its misuse. The last four lines of the section (10) are open to serious criticism.

Furthermore the high proportion of empty beds in cottage hospitals suggests that so far as possible it is desirable to discourage the multiplication of small local hospitals which in regard to equipment and staff are bound to be at a disadvantage compared with the larger hospitals.

The first part I have already dealt with. The statement as to equipment and staff is surely not correct, if we recognize, as we certainly should, the different functions of these two classes of hospital.

It is satisfactory that the Commission recognizes the futility of the proposal to relieve pressure by the transfer of patients from one hospital to another, an oft-repeated suggestion that those actually engaged in the work must always have known to be impracticable.

The reconstitution of local committees, discussed in section 21, is highly desirable, and it is hoped that the general practitioners of the area, who are so largely concerned, will be well represented on these bodies. These committees will provide an opportunity for organizing what I believe to be the only sound financial system of maintenance—the promotion of local funds for hospital service, not for individual hospitals. Out of such funds would be paid the cost of the patients from the area of the fund, in whatever area they might be treated. Progress in this direction is already being made in many areas, and these local bodies will have great opportunities for developing the principle—I am, etc.,

Bradford on Avon Aug 16th

CHARLES E S FLEMING

INVESTIGATION OF RHEUMATOID ARTHRITIS AND ALLIED CONDITIONS

SIR,—We are much impressed with the valuable suggestion made by Dr Logan in his letter (JOURNAL, August 8th, p 271) as to the organization of research in chronic arthritis and allied conditions.

The importance of this subject is especially evident to us at the present time, as new laboratories were opened in this town at the Royal Bath Hospital on August 10th, liberally equipped for routine examinations and research in bacteriology and biochemistry. The hospital contains 150 beds, almost wholly allotted to victims of this group of crippling diseases, who thus afford an ample field for observation.

We are conscious of difficulties in making a full use of our opportunity—difficulties which will be obvious to those who work among these patients. These difficulties might well become less perplexing were there taken some co-ordinated action, as indicated by Dr Logan, or, perhaps even better, should the Medical Research Council offer some active interest in the group of disabilities which is such a wide spread cause of individual suffering, and also, as Sir George Newman has emphasized, of industrial unfitness—We are, etc.,

Hospital

August 10th

THE POWER OF IRRATIONAL BELIEF

SIR,—Owing to the malevolent activities of certain evil forces I was unable to listen to Dr Barnes's sermon at Bath, but I have read your report of the sermon and your leading article. Clearly, both you and he are off the rails! You say that superstition is the bane of medicine. He deplores the recrudescence of "thick disguised magic in worship."

Where, SIR, should we be if the public ceased to be superstitious? At the moment those of them who are not panel patients do believe in us. They consult us, they accept what we say, they pay us fees. Why? Because they are convinced that we have certain occult knowledge denied to them, because we can supply them with diagnoses wrapped up in the most impressive terms. They do not ask us to be scientific. They are justly suspicious of us when we are scientific. They know that the "scientific" doctor will either (1) squirt things into them, or (2) cut things out of them. They do not want that. What they do want is a bottle. In other words, they ask for something

magical. And those of us who are sufficiently unscientific, and vain, to supply it get the results, though as a rule we remain miserably poor.

As for Dr. Barnes—he is up against magic. Strange! For magic means wisdom—the cult of the wise men. It has no concern whatever with cold material fact. It is almost as old as the human race. And magic is the fundamental basis of both religion and medicine.

But few realize this except parish priests, general practitioners, and wise old women—I am, etc.

Walsall, Aug. 5th

FRANK G. LAYTON

ULTRA-VIOLET LIGHT

SIR,—In reply to Dr. Blakiston's letter published in your issue of August 8th (p. 272) with regard to the cost of electrodes in a tungsten arc lamp.

1 The current passing through the lamp which we use is 5 amperes. The town's electrical supply is one of 225 volts direct current.

2 Two pure swaged tungsten electrodes are used.

3 We spent £9 16s. 10d. on electrodes from the opening of the clinic April 8th 1924 until June 30th 1925. There are two sessions per week and we estimated that the lamp was actually in use for 14 hours each session. There is a possible fallacy in that the length of time the lamp was actually burning during each clinic was overestimated but this cannot be serious, and the clinic nurses consider that two hours would be more accurate than 1½ hours. On the basis of 14 hours per session the estimated time the lamp was in use was 189 hours from which the figure of 1s. 0d. per hour was obtained.

The tungsten electrodes now cost 4s. an inch which would mean an average consumption of 1/8 in. per hour per electrode. An endeavour was made to check this by burning the lamp for an hour and measuring the loss. It was realized at once that this was an inaccurate method as the electrodes burned very irregularly and in a caterpillar-like fashion but even where the electrode had been burnt most the loss did not exceed 1/4 in. on one of the electrodes and less than that on the other.

It appears to be quite obvious that the lamp used by Dr. Blakiston which burns 1½ in. per hour must be dissimilar from that used at the Hull clinic—I am, etc.,

Hull Aug. 15th

W. ALLEN DUFFY

SIR—The correspondence in your columns on the cost of tungsten exposures has interested me.

For some time past I have been using electrodes of tungsten-steel in conjunction with pure tungsten one of each kind conjointly on a 5 ampere current. This has reduced the cost of working by, I think I can safely say 50 per cent. The efficiency is good, and whilst it may be necessary to give slightly longer exposures, even so the cost is less than when using pure tungsten only.

In view of the present position in the tungsten markets this information may be of use to other workers. These tungsten-steel electrodes can be obtained from Messrs Arnold and Sons, 50, Wigmore Street, London, W.1—I am, etc.,

London W. Aug. 12th

EDWARD JAMES DECK

PHYSICIANS OF MANKIND

SIR,—The interesting review in last week's JOURNAL of the life of Chadwick and the work of Southwood Smith brings to mind these lines, written by Leigh Hunt and inscribed on the tombstone of Dr. Smith in the English cemetery at Florence. They are applicable to both Chadwick and Smith.

"Ages shall Cherish in their hearts Fashined,
These Southwood Smith Physicians of Mankind,
Bringer of Air, Light, Health into the home
Of the Rich poor of happier years to Come."

Concise, happily expressed, and let us hope prophetic—I am, etc.,

London W., Aug. 17th

D. COLQUHOUN

DISEASES DUE TO FASHION IN CLOTHING

SIR,—To the current discussion on chlorosis in your columns the following extract from Falstaff's soliloquy in praise of sack (*Henry IV., Part II Act IV, Sc 3*) seems pertinent as indicating that the condition was of common

occurrence at the time the play was written (about 1593), and that it was popular belief that underfeeding was causal.

There's never none of these dainty boys come to any proof, for this drink doth so over-cool their blood and making many fish-morls that they fall into a kind of male green-sickness and then when they marry they get wench.

—I am, etc.,

Stafford Aug. 3rd

A. I. HODDER

REPRESENTATION ON THE COUNCIL OF THE SOCIETY OF MEDICAL OFFICERS OF HEALTH

SIR,—In the report of the meeting of the Council held at Bath on July 22nd (printed in the *STANDARD* of August 15th, p. 87), some observations with regard to the representation of the British Medical Association on the Council of the Society of Medical Officers of Health are attributed to me. The remarks were made, not by me, but by my colleague, Dr. C. L. S. Hemming and I am not in agreement with them as far as they refer to part-time medical officers of health. It seems to me that no man can better act as "honorary officer" between two such societies than one who has intimate knowledge of the views and outlook of the respective parties together with practical experience of the varied difficulties peculiar to each—unless indeed it is suggested that loyalty to the British Medical Association is, on the part of such, impossible—I am, etc.,

Bristol Aug. 17th

T. RIDLEY BARRY

The Services

DEATHS IN THE SERVICES

Surgeon Lieutenant Colonel Heinrich Friedrich Lwartz Mollath, A.M.D. and Royal Horse Guards (ret.) died at Chelsea on June 4th aged 82. He was educated at Edinburgh where he graduated M.D. in 1863 and took the L.R.C.S. in 1864. He entered the army as a student surgeon on March 31st 1864 and a regimental officer served for some years in the 12th Linc. R. On October 11th 1876 he was appointed surgeon to the Royal Horse Guards, the illness becoming surgeon-major on September 4th 1890 and surgeon lieutenant-colonel on March 31st 1894. He retired in July 1897. He served on the North West Frontier of India in the Bhutan campaign of 1865 receiving the frontier medal with clasp, in the Tirah campaign of 1870-71 with the British Field Ambulance and in the Nile campaign of 1895 with the desert force when he took part in the action at Korti and received the medal with a clasp and the Khedive's bronze star.

Major Charles Stuart Spang D.S.O. R.A.M.C. (ret.) died at Sargatta, Chaux, Switzerland on July 12th aged 66. He was born at Laversham the son of Mr. W. Nash Spang F.R.C.S. He was educated at Ipswich College and at Guy's, and took the B.Sc. Lond. in 1880 the M.B. Ch.B. and L.S.A. in 1884 and the L.R.C.S. in 1889. He entered the army as surgeon in 1887 became major after twelve years' service, and retired on August 16th, 1899. In 1899 he was seconded for service with the Egyptian army and saw much active service during the campaigns of the nineties of last century. The Dongola expedition of 1896 the Nile campaign in 1897, when the battle of Atbara was fought and Kitchener's final campaign of 1898 ending with the battle of Omdurman, where he was senior medical officer of the 1st Egyptian Brigade. He was mentioned in despatches on November 3rd 1896, January 25th May 24th and September 30th 1898. He received the Nile medal with six clasps, and the Khedive's medal also the Medjidie 4th Class in 1897 and the D.S.O. in 1898. After returning from the army he became medical adviser to the Egyptian railways. He rejoined for service in the late war and was mentioned in despatches on June 21st 1916. In 1900 he married Mary Barosky, daughter of the late Henry Pickering of Titusville, Pennsylvania, and leaves one daughter.

Major Joseph Ophimo Pinto Midway Medical Service (ret.) died on April 20th aged 64. He was born at Silvette Bombay and educated at the Grant Medical College there where he took the L.M.S. in 1883 and at St. Thomas's and Edinburgh, taking the Scottish triple qualification in 1887. He entered the I.M.S. as surgeon in 1887 became major after twelve years' service and retired in 1906. He served on the North West Frontier of India in the campaigns of 1897-98 taking part in the operations on the Samana range and in the Kurram valley (medal with two clasps) and in Tirah in the regions of Chagru Kotial and Dargu, and the operations in the Bazru Valley (clasp).

Captain John Power Carmody late R.A.M.C. died at London on June 14th aged 68. He was born on November 17th, 1856 educated at Queen's College, Cork, and graduated M.D. and M.Ch. in the Queen's University, Ireland in 1877. He entered the R.A.M.C. as surgeon in 1880, was placed on half pay, on account of ill health, in 1888, and retired in 1893.

Obituary

WALTER CARLESS SWAYNE, M D, B S Lond,
M D, Ch B Bristol,

Professor of Obstetrics in the University of Bristol,
Consulting Obstetrician and Gynaecologist to
the Bristol Royal Infirmary

We regret to record the death of Dr Walter C Swayne, professor of obstetrics in the University of Bristol, at the age of 63. He met his death in sadly tragic circumstances in his daughter's house at Sellick, near Ross, Herefordshire. It appears that his son-in-law, Mr R L Wreford Brown, on the night of August 13th, alarmed the household by firing revolver shots at random in his room. Dr Walter Swayne courageously attempted to disarm him, and received several shots in the abdomen, which proved fatal in a few hours. At the inquest on August 15th a verdict of murder was returned, but the coroner said that at the assizes evidence would certainly be put forward that the accused was insane.

Dr Swayne's death is a great loss to the whole profession, and more particularly to the West of England, where he occupied a leading position as an obstetrician and gynaecologist. He was born on April 19th, 1862, at Mathon in Worcestershire. He was the eldest son of Mr R A Swayne, of Tillington Court, Hereford, and a nephew of the late Dr Joseph Griffiths Swayne of Bristol. He received his education at King Edward's School, Birmingham, University College, Bristol, the Bristol General Hospital, and Guy's Hospital. He represented Guy's at Rugby football and on the river—in fact, it was due chiefly to his energy that the rowing club was revived at Guy's. In 1888 he was resident obstetric officer at the hospital. Shortly afterwards he commenced to practise in Clifton, and, following the example of his uncle, soon made his mark as an obstetrician. In 1891 he succeeded Dr J Wedmore as obstetric physician at the Bristol Royal Infirmary. This post was a comparatively new one, having been first created in 1887. Dr Swayne experienced at the Royal Infirmary the usual amount of opposition to the establishment of the specialty of gynaecology, and it was not until 1904 that the infirmary rules were altered to permit of the gynaecologist performing abdominal operations. When this permission was granted Swayne's operating theatre was organized by him on the modern aseptic lines, and his theatre "drill" was always unapproachable, even though the novelty of clothing the on-lookers as well as his assistants in gowns, caps, and masks excited at first some ridicule. It is worthy of note that although Swayne found himself opposing and opposed by his colleagues in his long struggle for the right of a gynaecologist to perform major operations, his friendships with them never suffered. He was always "Dicky" Swayne to his opponents in the midst of hot controversy. In the end he succeeded in establishing a model department of midwifery, both internal and external, and of gynaecology.

Dr Swayne contributed many articles to medical journals on obstetrics and gynaecology. Some of his more important dealt with eclampsia and its biochemical problems. He often expressed his regret that he had begun to grow old in his profession before biochemistry came into being, so that he lacked the requisite training for research in a subject that interested him so greatly. In 1913 he edited the eleventh edition of his uncle's famous book, *Swayne's Obstetric Aphorisms*.

Swayne was elected professor of midwifery in University College, Bristol, in 1902, and was continued in this chair when the university was incorporated in 1909. He was an admirable teacher and a most loyal graduate of the new university, for he took the *ad eundem* degrees of M D, Ch B, at the earliest opportunity in Bristol on the strength of the degrees he already held from London University. He was an enthusiast in fostering a corporate spirit amongst the new graduates of Bristol, and was an ardent champion of the rights of convocation, the representative body of the graduates. In the earliest days of the university he was unsparing in his criticism of the supreme authorities for their singular action in electing as pro-

fessors all who had occupied chairs in University College, with the one exception of the professor who had been secretary of the committee for promoting the foundation of the university. Swayne was keenly interested in the medical education of women, and the first woman resident at the Royal Infirmary was appointed to his obstetric department.

One of the most striking features in Swayne's professional career and in his character was his total lack of anything like jealousy for his younger colleagues and possible rivals in his own specialism, and it was with great pride that he used to watch the progress of his pupils, Miles Phillips and King in Sheffield, Giceu-Amytge in India, and Statham in Bristol.

Outside of his profession Swayne's chief hobby lay in soldiering. He was a keen student of military history, and early in life joined the Gloucestershire Artillery Volunteers as a boy trumpeter. He eventually rose to the rank of major in the Territorial Artillery, and received the Volunteer Decoration after twenty years' service. At the commencement of the war he was transferred for a time to command the Bristol University O T C and was instrumental in developing in connexion with it an enthusiastic company of "volunteers" amongst men who were over military age. Subsequently he raised the third line of the South Midland R F A, and finally commanded a battery of New Zealand artillery on Salisbury Plain, which he had the satisfaction of conducting overseas to France, although to his lasting regret his age debarred him from remaining to serve with the battery at the front. In addition, Swayne was a keen Freemason and had been master of St Vincent Lodge in Bristol and a grand warden in the province of Bristol. His chief sport in his later years was trout fishing, and in his country wanderings with his rod he used to search out and study any remains of the Roman occupation of Britain that came his way.

At the time of his death Dr Swayne still occupied his chair in the university and was in charge of the clinic for venereal diseases at the Bristol Royal Infirmary, a department which he had organized since the war with his customary thoroughness and administrative ability. He had retired from the active staff of the infirmary as obstetrician and gynaecologist in 1924, and held the office of honorary consultant to that institution.

In 1912 he occupied the presidential chair of the Bristol Medico-Chirurgical Society. He had been at different times an examiner in the Universities of London, Birmingham, and Leeds. Swayne was a man of most lovable disposition, who retained throughout life his boyish enthusiasms.

In 1894 he married the daughter of the late Rev R F Heath. His widow, with three daughters and a son, survive him, and we offer them our deep sympathy in their sad bereavement.

CHARLES LLOYD TUCKEY, M D

Dr LLOYD TUCKEY passed away at his residence, Ingaisby, Eastbourne, on August 12th, aged 70 years. He had retired from practice and had been in poor health for the past twelve years, but continued his interest both in psychotherapy and in psychical research.

He was of Anglo-Irish stock, and was the eldest son of his father—a graduate of Trinity College, Dublin, who practised at Canterbury. Lloyd Tuckey was educated there, at King's School, later at King's College, London, and at the University of Aberdeen. He graduated M B, C M in 1875, and M D in 1884. He was early attracted to treatment by suggestion. He studied hypnotism in 1888 under Liebreault at Nancy, and may be said to have been one of the pioneers of hypnotic treatment in England, being closely followed by the late Dr Milne Bramwell. Lloyd Tuckey started this work in London in 1878, and was always courteously willing to demonstrate his methods to medical men and students.

Lloyd Tuckey was a man of broad sympathies, wide culture, and distinct literary ability. A tall, genial, hand some man, he was quite a contrast to the popular idea of a professional hypnotist, and used to say that success in

his specialty was largely due to a kindly and sympathetic manner. This to an eminent degree he possessed, but had he been more mysterious, and commercially more acute, he would probably have been more financially successful. His book, *Treatment by Hypnotism and Suggestion, or Psycho-therapeutics*, now in the seventh edition, brought him international recognition. Articles from his pen appeared in the *Nineteenth Century* on "Hypnotism in chronic alcoholism," in 1888, and "Truth healing as a medical treatment," in 1892. In 1889 the *Lancet* published "Cases treated by hypnotic suggestion," and *Brain* in 1891 printed his "Critical digestion of hypnotism," and the *Practitioner* "Hypnotic suggestions in neurasthenia."

As the cases in his book show, he had some success in the treatment of alcoholism, and was elected an honorary member of the American Society for the Study and Cure of Inebriety. He was one of the founders of the Society for Psychical Research, and was for many years a member of the council of that body of which he was afterwards elected an honorary member. His retirement took place at a time when the newer psychotherapeutic measures were coming before the profession, and, though interested, he was chary of expressing an opinion as to their remedial value. The chronic cases he published in his book and elsewhere have particular value to those who knew him as a man of unerring truth and honour.

Late in life, in 1915 he married Beatrice Mary, daughter of the late Robert Wood Marsland, solicitor, of London, who nursed him with constancy and patience during his long illness.

Dr EDWARD JOHN LEWIS, who died on June 8th, aged 65, received his medical education at Cambridge and St. Bartholomew's Hospital. In 1883 he obtained the L.S.A., and in 1884 the M.R.C.S. diploma, he graduated M.B. Cantab. in 1887, and obtained the F.R.C.S. Eng. in 1890. He held the posts of house surgeon at St. Bartholomew's Hospital, and senior resident medical officer to the Hospital for Children, Great Ormond Street, and he was later appointed consulting physician to the Kilburn Dispensary and the Clergy Orphan School. His practice in Hamilton Terrace was very large and was chiefly devoted to diseases of children. In his younger days Dr Lewis was a Welsh international footballer, and in later years he distinguished himself at golf. He was a member of the British Medical Association.

We regret to report the death of Dr RICHARD MANNER HENRY RANDALL, at the age of 63, after a short illness. Dr Randall was a son of the late Surgeon-Major H. L. Randall of the Straits Settlements and received his medical education at Guy's Hospital. In 1884 he obtained the diploma M.R.C.S., and in 1885 the L.S.A., he graduated M.B. Lond. in the latter year, with honours in forensic medicine and materia medica, and took the M.D. in 1887. In 1888 he started practice in Beckenham and was associated with the local administration for many years, being chairman of the urban district council in 1902, and again in 1919. During the war he was for some time honorary medical superintendent of the Beckenham Red Cross Hospital, in 1918 he was mentioned in dispatches, was awarded the M.B.E., and received the King Albert bronze medal, of which only eleven were given, for his services in connexion with Belgian refugees. He was honorary consulting medical officer to the Beckenham Cottage Hospital, and medical officer to the Beckenham Provident Dispensary and Balgown Hospital.

Dr EVELYN OLIVER ASHF, who died at Kimberley on April 27th, aged 61, received his medical education at the London Hospital and Owens College, Manchester. He obtained the diploma L.S.A. in 1888, and graduated M.B. Lond. with honours, in the same year. In the following year he took the M.D. degree, and obtained the F.R.C.S. Eng. in 1892. After holding house appointments at the London Hospital he went to Kimberley in 1892, as senior house-surgeon to Kimberley Hospital, he

started general practice about two years later, but retained his connexion with the hospital as surgeon. He was also surgeon to the De Beers Consolidated Mines, Kimberley. He became a member of the British Medical Association in 1890. He was very highly esteemed in Kimberley, the funeral procession was nearly a third of a mile in length and included the mayor, ex-service men, nurses, and scouts.

A colleague writes: As a student Dr Ashf distinguished himself in everything that he took up, and those who knew him at the London Hospital will not easily forget the tall, manly figure and cheery face, he was always ready to help any fellow student in difficulties of any kind. He had an unborn love of the sea and took a long whaling trip before settling down in practice. Outspoken, bluff, fearless, adventurous, with a high sense of humour, great kindness of heart, and boundless generosity, he had all the qualities of the best type of Englishman.

Dr R. M. TAWSE, who died on March 5th at Cape Town after a long illness, received his medical education at Aberdeen, where he graduated M.B., Ch.M. in 1888, proceeding M.D. in 1891. He had been in practice in Rhodesia for twenty-seven years, was a railway medical officer, and justice of the peace in Matabeleland and the Bechuanaland Protectorate.

Professor AUGUSTUS STEVENS, a well known physiologist of Padua, has recently died.

Medical News.

THE second list of subscribers to the Sir John MacAlister memorial fund contains sixty-nine names. The fund amounts to over £700, and the committee is therefore now justified in taking steps to obtain a good portrait.

THE new quarters of the Marine Biological Laboratory at Woods Hole, Massachusetts, were formally opened on July 3rd. The laboratory, the *Journal of the American Medical Association* states, grew out of the influence exerted on biology by the little group Louis Agassiz assembled at Penikese Island half a century ago. After pointing out the relations of biology, even of the humblest organisms, to medicine, our contemporary states that with the plant and investments it now possesses "the Woods Hole organization approaches the foremost rank among the world shops devoted to the study of living nature. There investigators representing the advance guard of the biologic sciences can find welcome, opportunity, unique facilities, and personal stimulus for the exploration of protoplasm in its varied manifestations." We have received from the librarian of the laboratory a request for reprints, which will be filed in its library.

Dr W. H. DICKINSON, tuberculosis medical officer for Newcastle upon Tyne, has contributed to the issue of *Lubercle* for August an article on the interchange of specialist medical officers under a scheme of the League of Nations Health Organization. The first interchange of tuberculosis medical officers took place early in 1924. Delegates from thirteen countries, accompanied by Dr. Rulot of the headquarters staff of the Health Section of the League, visited eight countries, and studied the organization of the antituberculosis campaign in each. Dr. Dickinson was struck by the absence of any comprehensive system of notification in any of the Continental countries visited. He notes that the recumbent position is a much more prominent feature in treatment on the Continent than in Britain. He found that it was recognized everywhere that sanatorium treatment of definite (that is, sputum positive) cases of pulmonary tuberculosis, except for the purpose of isolation, plays a very minor part in the prevention of tuberculosis. He observes, also, that lack of sunshine is by no means the only factor adverse to the abolition of tuberculosis, since the mortality is lowest in Holland, Belgium, and Britain, all industrial countries with atmospheric pollution and damp, foggy weather. In view of the recent discussion on pure milk at the Annual Meeting at Bath, it is interesting to find that very little attention is paid on the Continent to the prevention of the sale of milk from tuberculous cows.

SIR STCLAIR THOMSON has been appointed honorary consulting laryngologist to the Italian Hospital, London.

THE Fellowship of Medicine announces that a two weeks intensive course in general medicine, surgery, and the specialties at the Queen Mary's Hospital, Stratford, will begin on August 24th. From September 21st to October 3rd the Brompton Hospital will hold a special course in the various phases of pulmonary diseases. The Infants Hospital and the Hospital for Diseases of the Skin, Blackfriars, both begin courses on September 7th for two weeks each. A course in ophthalmology will be arranged at the Royal Westminster Ophthalmic Hospital for three weeks from September 7th, and there will be a series of weekly lecture demonstrations on electrotherapy at the Royal Free Hospital from September 23rd to October 14th. An intensive course, covering general medicine, surgery, and the specialties, will be held at the Westminster Hospital from September 21st to October 3rd. Additional information about these courses may be obtained from the Secretary at 1, Wimpole Street, W 1.

THE Joint Tuberculosis Council has arranged two post graduate courses for medical officers engaged in tuberculosis work. (1) A fortnight's course, limited to six members, in the pathology and bacteriology of tuberculosis, conducted by Dr Roodhouse Gloyne at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, from Monday, September 21st, to Saturday, October 3rd. The class will meet in the mornings or in the afternoons, according to arrangement. (2) A course, limited to thirty members, on non-pulmonary tuberculosis, and lasting one week. On Monday, September 28th, the members will visit Heatherwood Hospital, Ascot, and on the following day Queen Mary's Hospital, Carshalton. On Wednesday and Thursday the members will meet in the morning in the skin department of the London Hospital and on Wednesday afternoon at the Royal College of Surgeons. On Thursday afternoon they will visit All Saints' Hospital for Genito-Urinary Diseases. On Friday and Saturday they will visit the Wingfield Orthopaedic Hospital, Oxford. Further particulars can be obtained from the Honorary Secretary, Dr William Braud, 19, Brunswick Square, Cambridge, S E 5.

A COURSE of lectures on child welfare for health visitors, nurses, midwives, teachers, and voluntary infant welfare workers, will be given at University College, Nottingham, in the week beginning September 21st. Full particulars can be obtained from the Honorary Secretary of the National Association for the Prevention of Infant Mortality, 117, Piccadilly, London W 1, or from Miss Adams, Health Department, Guildhall, Nottingham.

INTERNATIONAL post graduate courses will be held in Berlin during October. They comprise medicine, surgery, and the specialties, including ophthalmology. Further details may be obtained from the Honorary Secretary of the International Post Graduate Courses, Kaiserin Friedrich Haus, Luisenplatz 2-4, Berlin, N W 5.

THE seventh international post graduate course in balneo-logy and balneotherapy will be held at Carlsbad from September 15th to 19th. Further information can be obtained from Dr E. Grunz, Carlsbad.

THE jubilee of the foundation of the French University of Beirut is shortly to be celebrated. The faculty of medicine was instituted in 1888, and since 1898 its medical students have been able to obtain the French diploma. The school of pharmacy was inaugurated in 1889, the antibiotic institute in 1913, a research institute in chemistry and bacteriology in 1919, a dental school in 1920, and a training centre for midwives in 1922. A fine modern hospital was added in 1923. The university receives students from a wide area extending from Cairo to Bagdad, and even Angola.

A PARTY of public health statisticians has recently visited Great Britain under the auspices of the League of Nations, the countries represented were Austria, Belgium, Denmark, Finland, France, Germany, Norway, Sweden, Switzerland, the United States, Chile, and Poland. There were also two representatives of the League of Nations. They had opportunities of conferring with Dr T. H. C. Stevenson, C B E., of the General Register Office, and Dr J. C. Dunlop, Registrar General for Scotland. The party was entertained by the Government at a luncheon last week, when Sir Kingsley Wood, who proposed the toast of "Our Guests," said he was glad to think that the important work the League of Nations was doing in the field of public health had taken its origin in conferences held at the Ministry of Health and that the British Government had always been in the forefront of the movement. Dr J. Stouman, a member of the Health Section of the League of Nations, in expressing on behalf of himself and his colleagues appreciation of the welcome they had received, said that the party, which had toured widely in Northern Europe, fully appreciated that it was in Great Britain that, by the work of an expert committee, the Health side of the League of Nations was first set afoot.

DR J. P. WALKER, Secretary of the South Essex Division and the Representative of the Division in the Representative Body of the British Medical Association, has been appointed a justice of the peace for the county borough of Southend-on-Sea. Dr L. Stanley Robinson of Stourport has also been appointed to the Commission of the Peace for the County of Worcester.

DR J. H. WILLIAMS, M.P., has issued a letter calling attention to the number of cases of suicide by poison. It is not, he says, the primary poisons that are guilty (their restriction has served its purpose well), but the ordinary "household" poisons, of which spirits of salt is the chief. This can be sold by any shopkeeper as long as it is contained in a poison bottle and labelled "poisonous," and with the name and address of the seller. These restrictions are not enforced and are consequently disregarded every day. This indiscriminate sale of poisons, for which there must be substitutes for household use, constitutes a grave public danger, and calls for the action of the authorities in enforcing the law as it stands or restricting the sale with the utmost stringency.

A COURSE of lectures and demonstrations in hospital administration for the diploma in public health will begin at the North Western Hospital, Hampstead, on October 1st. Further information can be obtained from the Clerk to the Metropolitan Asylums Board, Victoria Embankment, L C 4.

MR JOHN ROCKFELLER, JUN., has presented the Imperial University of Tokyo with 1,600,000 dollars to replace the library destroyed by the earthquake and fire. The new library will provide space for a thousand students.

THE Home Secretary has issued regulations, dated July 27th, limiting the weights which may be lifted by hand by any person engaged in the woollen and worsted textile trade.

MESSRS T. M. BERN, established as chemical manufacturers for more than half a century in Fenchurch Avenue, have removed their head office to 106, Fenchurch Street, E C 3.

THE Académie Française has awarded the Bordin prize to the well known psychiatrist Dr Maurice de Fleury, member of the Académie de Médecine.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W C 1**.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square W C 1 on receipt of proofs.

All communications with reference to **ADVERTISEMENTS** as well as orders for copies of the **JOURNAL** should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSFUM 9361 9362 9363**, and **9364** (internal exchange four lines).

THE **TELEGRAPHIC ADDRESSES** are
EDITOR of the **BRITISH MEDICAL JOURNAL** *Antology Westcent, London*

FINANCIAL SECRETARY AND BUSINESS MANAGER
(Advertisements etc.), *Anticulate Westcent London*

MEDICAL SECRETARY *Vedusecu Westcent London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus Dublin* telephone 4737 Dublin) and of the Scottish Office 6 Drumshugh Gardens, Edinburgh (telegrams *Associate, Edinburgh* telephone 4361 Central).

QUERIES AND ANSWERS

THE LOCOMOTENT'S OWN CAR

A CORRESPONDENT states that last year when acting as locomotient he found principals who would have been glad if he had brought his own car. He would like to have opinions as to the allowance which should be paid by principals to locomotients or assistants who may have to provide or advertise that they will provide their own cars.

PIGMENTATION AFTER DIPHTHERIA

DR J. EVANS (North) asks for suggestions with regard to the cause of pigmentation in the following case. A highly strung boy aged 7, the child of very nervous parents, contracted diphtheria, and was given 16,000 units of antitoxin intramuscularly.

No untoward symptoms supervened and the throat rapidly cleared. Seven days after the injection yellow staining of the circumoral and palmar regions was noticed, it lasted for four days but was not attended by signs or symptoms of any local or constitutional disturbance. It cleared completely, leaving neither pigmentary changes nor desquamation.

PNEUMOCOCCAL MENINGITIS

Dr DUDLEY GILL (West Bromwich) writes: Early in March a youth, aged 14½ years, fell from a ladder about 20 ft high whilst at work, he sustained cerebral concussion and superficial injuries to mouth and face. I attended him for about three weeks; he then returned to work and appeared to be quite fit and well. On April 29th he went home from the cinema and retired to bed. At about midnight he complained of severe headache, became restless and feverish, and at 12.30 vomited three times. When I saw him at 9.30 a.m. he was extremely ill, the temperature was 105½, pulse over 120, but a respiration was present. The muscles of the trunk and limbs were in a state of tonic spasm, the pupils were dilated and reacted sluggishly, head retraction was not marked. At noon on the same day his condition was considerably worse, he quietly became comatose and died at 9.20 p.m., the total duration of the illness was about twenty hours. At the autopsy there was no evidence of cerebral injury, inflammatory exudate was present over the brain, especially marked over the vertex. The cerebrospinal fluid was turbid, contained a large excess of albumin, a large number of polymorphonuclear cells, and numerous Gram positive diplococci, which proved to be pneumococci. In this case the meningeal infection was undoubtedly primary. In view of the fact of the boy having had an injury to the head six weeks previously, the question arose as to whether the cerebral injury had any relation with the death caused by the pneumococcal meningitis. It is a point I am doubtful about, and I should be very pleased to hear the views of any medical men who have had similar cases.

INCOME TAX Depreciation of Car

"S C" has agreed his average assessment for 1925-26 with the inspector of taxes, to include the deduction from the 1924 receipts of the cost of replacing his old car. Is he entitled to a depreciation allowance for 1925-26?

* * * Yes, the fact that the cost of replacing the old car has been dealt with as an expense does not affect the allowance due for his present car. The amount to be claimed is, as suggested, 15 per cent of the cost, £375—that is, without deducting the £100 received for the sale of the old car.

Change in Partnership Share

"PUZZLED" sends the following inquiry: A and B divided the profits for the year 1924 on the basis of half shares, in previous years the shares had been two thirds and one third respectively. How should the liability be divided?

* * * For 1924-25 each should account for tax on a half share of the gross assessment, deducting therefrom his own personal allowances, etc. The three years average is for the determination of the amount to be assessed on the firm, but it is provided in the income tax Acts that the assessment shall be divided between the partners in the same manner as the profits of the year.

LETTERS, NOTES, ETC

SUBNORMAL TEMPERATURE

Dr J. S. PEARSE (Plymouth) writes: With reference to "P. X. D.'s" inquiry (BRITISH MEDICAL JOURNAL, July 25th, p. 184), and Dr S. Vere Pearson's statement on the subject of subnormal temperature (August 8th, p. 278) may I draw their attention to a book recently published by Hutchinson entitled *A Doctor's Diary*, wherein the writer discusses various subjects, and states "that people with slow pulses and low temperatures are more likely to be intelligent than the ordinary run of humanity." If this is so "P. X. D." may take heart of grace and congratulate his patient on having a low temperature, with, peradventure, a slow pulse, being otherwise fairly fit he may be the possessor of more intelligence than his neighbours.

DRYNESS OF THE MOUTH

Dr JOHNSON SMYTH (Bournemouth) wishes to point out the efficiency of the mountain ash berry as a salagogue. It is perhaps the best of all salagogues. Now is the best time of year, before the berries get too ripe, to pluck them for preservation. A supply is being sent to Mr. Martindale 10, New Cavendish Street, London, W.1, who will preserve them and supply the profession.

RADIOTHERAPY IN MALIGNANT DISEASE

We have received from Dr S. P. IMPEY (Cape Town) some notes on 'A general survey of radiotherapy in malignant disease' by Dr S. Gilbert Scott, which was published in the JOURNAL of March 28th (p. 596). Dr Impey agrees with the author of the paper that to call cancer a local disease is only true within narrow limits, but considers that Dr Scott's further statement—that the cancer starts as a local disease but becomes general afterwards when the cancer cells are scattered through the body—is only part of the truth. In the course of his notes Dr Impey makes the following observations:

I believe cancer is a general disease from the start and the tumour a local manifestation of it. Cancer is due to certain changes in the blood, but, in addition to this predisposing cause requires an active cause to produce the tumour, and that is injury generally in the form of prolonged irritation. The changes in the blood which predispose to cancer are many, but may all be classed under one heading, and that is "blood poisoning." Some of the causes have been proved by experiment and observation, but I feel sure that there are many others which we do not now suspect. If cancer is a general disease, and only the local manifestation is treated, if a second proof occurs it may be only a continuance of the disease and not a recurrence. In the treatment of cancer it is, in my opinion, very necessary to attend to the condition of the blood, and even in very bad cases such attention causes a great amelioration of the symptoms, and in very mild cases seems to be almost all that is necessary to effect a cure. Dr Scott seems to imply that it is when a man becomes old and the tissues begin to degenerate that cancer is produced, but I think it is more likely that the real cause is overeating, which almost every old person indulges in. Dr Scott thinks that the morbid cells under the influence of the rays undergo a change which allows them to be absorbed and their place taken by healthy cells. I place is true, but I think not in the should in my opinion be treated. Inhibition of the growth of the cancer cells, and not their destruction. In all quick-growing tumours the rays act by inhibition and not by destruction. If no new cells are formed the old ones die and their place is taken by healthy cells. The healthy cells are not cancer cells which have been made healthy by the rays, but cells which have been supplied by the system. By using the inhibitive process in treating cancer nature is assisted, the cancer is cured without taxing the system to any dangerous extent, and the patient recovers without any bad effect.

TREATMENT OF TRACHOMA BY SUNLIGHT

Dr FORTUNATO PITTA (Lunchal, Madeira) writes: In 1917 I was called in to attend a young Portuguese child suffering from trachoma whose symptoms were getting progressively worse in spite of every treatment. I experimented the trachoma with carbonic acid snow and the condition improved to a certain extent, after two or three applications. I decided to try heliotherapy. The disease affected the upper eyelid, after protecting the globe as well as the lower eyelid I focused the sun's rays by means of a convergent lens on the trachomatous lesion. The first effect was a change in colour from red to chestnut and a profuse sero-purulent exudation, in a day or two the patient told me he was better and had awakened that morning without the eyelids sticking together, that the eyes were less red and that he could stand the light better. The application of the sun's rays was continued and the affection was rapidly cured. To day, some five years after, nothing is left of the trachomatous condition save a few quite superficial small white cicatrices. I have since used the same treatment in many cases of trachoma, none of which have lasted longer than three weeks, but the length of the cure depends upon the number of days on which it is possible to take advantage of the sun's rays, there should be applied in the early morning and if possible every day, this exposure should last one to two minutes. The disease here is widely spread in certain regions, and attacks a large number of persons.

THE POWER OF IRRATIONAL BRIEF

Dr J. KINELM RRID (Beckenham) writes: I read with much interest the sermon preached by the Bishop of Birmingham (JOURNAL, August 1st p. 225). There is one matter, however, which I suggest might with advantage be cleared up in order the case for freedom of thought, not even from an appearance.

Surely a very definite distinction can be drawn between (a) differences of belief and practice as evidenced among qualified members of the medical profession and (b) similar differences as evidenced among ignorant chaldeans. It is not suggested that the bishop is not keenly aware of this.

I know nothing of faith healing outside the profession of medicine, but I do know that it is practised by the successful physician. I know nothing of the merits of osteopathy, but I understand that cultured and fully qualified medical men have been known to practise it in all good faith. I know nothing of the different brands of chaldean psychoanalysis, but am convinced that it is not impossible to put psychoanalysis to good use in certain cases, indeed, it originated with our profession.

It seems to me that the force of the bishop's remarks would be enhanced rather than weakened if he made it quite clear that he was not in any way concerned with the profession's internal differences of opinion, but was simply championing the cause of knowledge and free thought as against ignorance and bigotry. It is unthinkable that he really intended his address to be a 'party address' rather than to represent the interests of the profession as a whole in relation to the question of ignorant quackery.

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments in hospitals will be found at pages 32, 33, 36 and 37 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 34 and 35. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 100.

British Medical Association

PROCEEDINGS OF SECTIONS AT THE ANNUAL MEETING, BATH, 1925

SECTION OF THERAPEUTICS
(INCLUDING BALNEOLOGY AND
RADIOTHERAPY)

Professor R. B. WILD, M.D., F.R.C.P., President

PRESIDENT'S OPENING REMARKS

PROFESSOR R. B. WILD reminded his audience that it was in 1887 that he gave his first paper before that Section to show how modern some of their methods of treatment were. He recalled that Professor Lieberich, the discoverer of chloral hydrate, attended the meeting and brought with him a specimen of lanoline, which he demonstrated. He congratulated the Section on meeting in the historic city of Bath, a city more devoted to therapeutics than any other. Many forms of treatment were offered there, and they exemplified what he had taught for thirty years—that it was better to rely on natural agencies than on drugs. The discoveries of the present day were the result of careful research. It was only occasionally that a new remedy was discovered empirically. They were now reaping the harvest of organized research begun in 1911 by the Medical Research Council. It was time to take stock of their knowledge. Asthma was one of the most fascinating diseases for everyone except the patient. Much had been done to elucidate its etiology. They needed to sum up what was known concerning treatment.

DISCUSSION ON THE TREATMENT OF ASTHMA

OPENING PAPER

BY

W. LANGDON BROWN, M.D. (Cantab.), F.R.C.P.,

Physician, St. Bartholomew's Hospital

THE treatment of asthma summarizes in itself, as it were, the chief trends of modern therapy: psychotherapy, sensitiveness to foreign proteins, vagotomy, and endocrine balance. But there has been a tendency on the part of enthusiastic workers in some one of these fields to neglect due consideration of the other aspects. Successful treatment involves them all.

Asthma may be defined as due to an unstable or unstable condition of the bronchomotor and visomotor portions of the vagus nucleus, which causes it to react unduly to physical or peripheral stimuli, or to foreign proteins in the circulating blood. This reaction can be expressed diagrammatically as follows:

I will first consider the stimuli acting on the centre, and then some features of its response.

1. Psychological Stimuli

That asthma often occurs in neuropathic families, and that asthmatics are unduly suggestible are well known facts. The pruritus excited by artificial flower figures in every textbook. But what is not so clearly recognized is that the effective stimulus often arises from a psychic conflict. Various influences will help to decide in which way a psychic conflict reveals itself. Thus one suffers from a psychic conflict who has to face a hostile environment may escape through a hysterical paralysis, but another who has to face the internal disorder produced by sensitiveness to foreign proteins is more likely to develop asthma.

2. Peripheral Stimuli

I have little to add to the common stock of knowledge of this subject. The influence of exertion, hay fever, and other nasal troubles, sinus infection, gastric and intestinal disturbances, and of uterine disorders is well recognized. But I should like to call special attention to enlarged bronchial glands, especially in children, and to suggest that this may explain the liability of healed tuberculosis to excite asthma in susceptible subjects. Interesting observations by Breckenridge show that peripheral irritation of the pleura, such as pleuritis, may excite an attack of asthma. In the epileptic a fit can be similarly produced which leads him to compare bronchial spasm to a localized epilepsy. Other points of resemblance between epilepsy and asthma will readily occur to you.

3. Foreign Proteins

Of recent years great attention has been paid to this factor. Morley Roberts has made the profound remark that "immunity is assimilation." There is one flesh of birds and another of beasts. From the welter of immunities which result from the disintegration of food proteins each animal has to build up its own characteristic and specific tissues. Specificity is chemical as well as morphological. To some foreign proteins we are naturally immune—that is we can assimilate them automatically, to others we acquire immunity—that is we learn to assimilate them. But to some foreign proteins immunity is neither congenital nor acquired. The tissues continue to resent the intrusion of such. They will not assimilate them. Such proteins excite anaphylaxis in varying degrees. Richet has defined anaphylaxis as the last stand of the race against adulteration of its protoplasm. In extreme degrees anaphylactic shock is fatal because assimilation would mean too profound an alteration of bodily structure. In less degrees anaphylaxis declares itself in violent attempts to get rid of the foreign invader. The asthmatic shows a sensitiveness towards such substances to which others are strangers. These substances are not in themselves toxic. Freeman injected into his own veins twenty times the quantity of grass pollen extract that would kill a sensitive person, and yet felt no effects from it. 500 units of pollen extract would probably kill a hay fever subject, but 20 million units have no effect on a rabbit. Such a result would be impossible with a really toxic substance. It is well known that many substances can act in this way, such as emanations from cats, horses, roses and other flowers, feathers, fungi, etc. On these facts the skin tests have been based. The test material is either applied to the skin after it has been lightly scarified or it is injected intradermally. A large wheal indicates a positive reaction. Van Leeuwen found that, whereas a positive reaction after scarification means hypersensitiveness, a negative reaction does not exclude it. The intradermal method, on the other hand, is not sufficiently specific. Only 2 to 3 per cent of his cases were really positive to the scarification test, while all his asthmatics reacted to a number (sometimes more than thirty) of antigens by the intradermal method but normal individuals did not. He concluded that while all asthmatics showed signs of hypersensitiveness, he was only able to determine the real causative agent in a small number of cases. This would accord with my experience that an asthmatic will give a strongly positive reaction to one substance at one time, and to another at some other time. It would appear that the asthmatic tendency shows itself in a general difficulty in dealing with a number of foreign proteins and only occasionally in a high degree of sensitiveness to a particular one.

Sometimes a foreign protein is sufficiently irritating in its effects to provoke a reaction in anyone, when it must differ from those described by Freeman, and be truly toxic. Thus Ancon came across an epidemic of asthma in a village near Florence and found that the grain was badly infected that year with a parasite. Everyone who handled this grain developed eczema, urticaria, or asthma. A less extensive and more endemic infection has been described by van Leeuwen which occurred in a small Zealand island. Here 1/2 to 1 per cent of the inhabitants of some villages became asthmatic. The Dutch climate in the ordinary

sense of the word, does not vary enough to account for this. He found in the gum of the district mites and fungi which would soon sensitize a considerable proportion of the population and produce asthma. On moving the patient to Switzerland he got rid of his asthma but even while there the inhalation of dust from the infected gum would within eight minutes excite a recurrence which lasted twenty-four hours. That the sensitive material was particulate was shown by the fact that if a cotton wool filter were introduced between the dust and the patient's mouth the attack did not occur. Some of the substances which excite asthma are definitely toxic in character. We are all familiar with the cases of severe bacterial infection of the upper respiratory tract which by prolonged lowering of resistance produce a sensitiveness resulting in asthma. I have also seen several instances of asthma coming on in adult life apparently due to the toxin of syphilis. I am inclined to think that the more toxic the substance the more specific the reaction while with antigens which are only effective with predisposed individuals the reaction may occur with any substance from a much larger group. It has of course long been recognized that if one product of an animal excites a reaction all its products will. The horse asthmatic is sensitive alike to the serum, the hair, and the urine of the horse; the patient sensitive to chicken will react even more to a hen's egg.

The Influence of the Parasympathetic

As Drury has expressed it, these toxic idiosyncrasies are conservative, self-repairing mechanisms under parasympathetic control. The great function of the parasympathetic may be defined as promoting the assimilation of suitable and the rejection of unsuitable material. Thus it starts the secretory and muscular processes of digestion, while it empties the rectum and bladder, and can reject food by vomiting. The excitation of bronchial activity and cough is similarly a method of ridding the body of unsuitable material, and it is interesting to recall in this connection that drugs which are expectorant in small doses are emetic in larger ones. And as for bronchomotor spasm, as Morley Roberts says, what is it but the violent overacting, as face tension pulling every cell in the small bronchi and alveolar spaces into its last form, is it tries to squeeze out mucus tries to defecate, so to speak?

Without accepting the whole of Lippinger's and Hess's theories we may agree that the asthmatic is a vagotonic, and is liable to other manifestations of vagotonia.

The Sympathetic and Endocrine Balance

But vagotonia may be relative as well as absolute. In other words, it may well be that in overacting vagus is due to diminished action of the antagonizing sympathetic. One of the ways in which the sympathetic carries out its defensive function is by activating those endocrine glands which flood the blood with sugar, and B. C. Roy has shown that in asthma the blood sugar is usually lower than normal. I believe that just as myelitis is associated with vagotonia, the opposite condition of sympathicotonia is related to immunity through the endocrine system. Not infrequently hypoadrenalism follows or accompanies myelitis, and certainly adrenalin has a valuable action in myelitic shock. It has a similar effect in some cases of urticaria. Huist considers that the toxic idiosyncrasies, including asthma, produce their effect, at any rate in part, by depressing adrenaal activity. He believes that the influence of fatigue in producing the asthmatic pruritus is capable of a similar explanation. Morley Roberts suggests that so might be the apprehensiveness so common in asthmatics. The over-activity of the broncho-constrictor fibres of the vagus is kept in check by the broncho-dilator action of the sympathetic, which the secretion of adrenaaline would stimulate. Hence the effect of an injection of adrenaaline, or of sudden fright, in checking an attack of asthma. Asphyxia has a similar action and produces the same effect, no doubt it is thus a factor in bringing the attack to an end without a fatal issue. I am aware that Steen and Rogoff deny this emergency action of adrenaaline, but Cannon's recent experiments have disposed of much of their purely destructive criticism. The liability of asthma to come on during sleep, when the para-

sympathetic gains the upper hand, further points to the influence of disturbed balance between the two principal branches of the visceral nervous system. The counter-ment of the adrenaal effect by pituitary may be held as point in the same direction. The glands which co-operate with the sympathetic—that is, thyroid, adrenals, and posterior pituitary—appear generally to help in checking the asthmatic pruritus. Thus Wedl has reported a interesting case of a sensitive asthmatic who developed myxoedema. Treatment by thyroid extract greatly relieved both conditions. The stimulating effect of the gonads in the sympathetic endocrine group may account for the influence of intermenstrual disease in exciting asthma. Certainly gonadal deficiency may be associated with thymic asthma, which is comprehensible, since the thymus is in infantile origin, apparently antagonistic to the gonads.

In general terms it would appear that when the endocrine balance sways in the direction of the vagus, asthma is likely to occur in susceptible subjects when the balance is reduced in favour of the sympathetic, attacks may be cut short or prevented.

Asthma, Erythema, and the Skin

The skin undoubtedly has excretory functions. Erythema is not uncommon in asthma. The rashes of the exanthemata have often been compared with that produced by serum in anaphylactic subjects. This conception of an excretory mechanism is expressed in the popular idea of the benefit derived by "getting the rash out." The toxin which cannot be assimilated—that is, to which the body is not immune—must be got rid of somehow, and, at any rate, from the vital structures. In this connection it is interesting to note the occasional alternation of attacks of eczema and asthma.

The condition of laryngismus stridulus is recognized as the infantile equivalent of asthma. It is further of interest to recall that both in skin diseases and in asthma cosmophilia is a usual feature of the blood picture. As an attack of asthma goes on and expectoration becomes more abundant, the cosmophilous pass into the sputum. I should regard the skin reaction of an asthmatic to foreign proteins as an attempt to wash out the offending non-assimilable material from the skin. MacLenzie Wallis has observed cosmophilism in the interaural wheals produced by this test. I think this all accords with the observations of Kitchin and Hardy, thirty years ago, on the role of cosmophilism in bacterial infections and intestinal digestion, which have passed into undescribed oblivion.

Application to Treatment

These considerations help to provide a rational explanation for some methods of treatment which have been empirically used in the past. I hope also that they may help to coordinate the views of those working at different aspects of the problem, and to emphasize the necessity for all-round assault on every case of asthma from the various aspects. The suggestibility of a patient should be utilized to help him confidently to expect a cure. But search must also be made for deeper-seated psychological troubles. Notably some of peripheral irritation must be eliminated, thus includes avoidance of late suppers and cold bedrooms.

Methods of desensitization by injection of very small doses have naturally been tried. The difficulty about any specific desensitization is considerable, both because the actual cause cannot always be found by skin tests and because hypersensitiveness is not always constant for one substance, but may affect a whole group. This is not so important as might appear, since non-specific treatment may also be successful. Thus, indeed, is the basis of treatment by protein shock, where injections of T. A. B. vaccine may excite the production of an antibody capable of dealing with an infection of unknown origin. In the sensitized asthmatic much smaller doses must be used to this end, since too large a dose will increase sensitivity. Peptone has been used in this way by Ankl, while van Leeuwen has used tuberculin largely, in addition to milk and sulphur. Out of 300 cases thus treated by the latter 50 per cent were quite or almost cured, 15 to 20 were not improved, while the rest were distinctly improved. The chief difficulty is

in the selection of the appropriate desensitizing dose, which may, in part, account for the great differences of opinion as to the value of this method. If filtering the air through cotton-wool will prevent attacks, an extract of the cotton-wool filter will contain the substance responsible, and can be used as a desensitizer. The effect of climate is recognized as very capricious. One patient had attacks at Cambridge in college, but not in lodgings near by. A family accustomed to take a house in Scotland for the summer were obliged to send the asthmatic member of the family to sample it before deciding on it. London suits many asthmatics, and some were benefited by the mephitic atmosphere of the old unelectrified Underground. To some extent this may be due to suggestion. An asthmatic goes to a place and gets an attack, therefore each time he goes there he expects an attack and has it. But van Leeuwen found that at a height of 4,500 feet above sea-level attacks were very rare. A return to the old environment will probably be followed by a relapse, perhaps in an exaggerated form, since some degree of immunity may be lost in the pure air freed from the substance responsible. But desensitizing procedures can be applied more vigorously in the higher altitudes, during freedom from attacks. Treatment by oxygen inhalations has been much exploited of late. They may act in the same way as pure or filtered air, but I think suggestion plays a part here. Mont Dore, in the Auvergne, has long enjoyed a reputation for the relief of asthma. This may be due partly to its altitude and partly to the inhalation of thermal gases which contain a perceptible amount of arsenic. So far we have no explanation of the way in which arsenic acts in this disease, though ever since the days of the Romans it has often been found to help.

The universal belief in the efficacy of the belladonna group in asthma finds its justification in the paralyzing action of such drugs on the parasympathetic endings, just as the filip given to the sympathetic by adrenaline or cocaine helps to redress the balance in another way. A combination of adrenaline and pituitin helps some patients more than adrenaline alone. According to some, the influence of iodide is mainly to activate the thyroid, if this is so the benefit of this drug in asthma is comprehensible, since the thyroid secretion lowers the threshold to sympathetic stimulation. The importance of doing everything we can to restore an impaired endocrine balance is, I think, undoubted.

I would summarize the treatment of asthma thus: consider the physical aspects of the case, remove sources of peripheral irritation, especially in the upper air passages, employ chest development exercises, especially in the young asthmatic, whose respiratory intake is usually poor, desensitize where practicable, restore the balance in favour of the sympathetic, and attend to the general hygiene.

This all-round attack on the problems of asthma seems to me to afford the best chance of relief, especially if carried out before structural changes such as emphysema have occurred. After that a vicious circle is set up which is hard to break.

GENERAL DISCUSSION

Dr F. P. POUTON (London), defining asthma as a bronchial spasm and a vasomotor turgescence said that there were several causes of this condition, and he would urge that asthma due to infection, whether from bronchitis or nasal catarrh, or the cardiac asthma of elderly patients (best treated by morphine or oxygen), should be sharply separated from the "allergic" type of asthma due to hypersensitivity. This group, of course, included, besides asthma, the other well known toxic idiopathies. They must admit with van Leeuwen that skin reactions were of no value in diagnosing the cause of the asthmatic attacks, but his extract of human dandruff might be of great value in determining whether a case was really allergic, and besides asthma, it might be used to separate off the allergic cases of epilepsy, migraine, urticaria and so on, from the remainder of these groups. Asthma was not due to urticaria any more than histamine shock was due to urticaria. The very fact that allergic individuals might be sensitive to drugs, such as aspirin,

was also a proof of this. The treatment might be directed to (1) the condition of the patient—specific or non specific—as described by Dr Langdon Brown, (2) keeping away from the specific exciting substance in Switzerland or other places where it did not occur, (3) to altering the receiving mucous membrane of the nose—for example, by touching certain spots with a cauterizer, (4) altering the condition of the bronchial muscle by subcutaneous injections of 1 to 5 minims of adrenaline to stop spasm, or 1 to 3 minims of caffeine, or by oxygen inhalation. He suggested that the psychic factor had been exaggerated, and was merely subsidiary in causing attacks when the other factors, the exciting substances and so on, were also present. In a similar way an attack of angina or diabetic coma might be precipitated by an emotional disturbance.

Dr P. HAMIL (London) said that from the opening communication it was clear that in the treatment of asthma there were a number of factors to be considered. A careful history would often give a very strong hint as to the nature of the protein to which the patient was sensitive. He might have learned by experience that contact with horses or the presence of a cat precipitated an attack. There might be a seasonal liability, and certain localities might predispose. Protein sensitivity tests might throw considerable light on the case, but there were patients who were sensitive to several proteins, and in such it was probable that there were proteins widely distributed, but not represented in our test series, to which they might respond. Dust was particularly liable to affect such widely sensitive individuals. If a clear and definite cause could be detected they should endeavour to remove it or avoid it (hose, cat, dog feathers), and to immunize the patient very gradually either specifically with minute doses of the offending protein or non specifically—as, for example, by means of peptone intravenously or by the oral route. It should be borne in mind that sensitivity to bacterial proteins could occur, and probably this was in part, at least, the cause of the asthmatic attacks of elderly chronic bronchitics. It was important in all cases to examine the sputum. Where the dominant infection was the *M. catarrhalis* immunization by means of vaccines was often strikingly successful. In pneumococcal cases the benefit might be considerable, but the immunity was short-lived and courses of inoculation needed to be repeated at intervals. Chronic bacterial infection rendered the patient more susceptible to foreign protein, either by maintaining sensitivity or exhausting the defensive mechanism (exhaustion of the sympathetic and its associated endocrines). Accordingly, attention should be paid to the respiratory tract as a whole, the upper air passages should be carefully examined for evidence of sinus disorders, and any defects or chronic infection dealt with. Dust occupations should be avoided. Bronchitic infections should be treated specifically, a matter of great importance in avoiding secondary effects and changes in the lungs. On analogy with what occurred in animal experiments and in hay fever they inferred that during an acute attack there occurred spasm of the muscle of the bronchioles and turgescence of the capillaries of the mucous membrane of the bronchioles similar to that which occurred in the nasal passages in hay fever, with outpouring of lymph into the tissues, the whole being analogous with wheals in the skin in urticaria and after the local application of histamine. These produced obstruction to the entry and still more to the exit of air, and distension of the lungs. Defective ventilation followed, with cyanosis, etc. The bronchioles could be relaxed by paralyzing the vagal terminations (atropine or hyoscine), by stimulating the sympathetic (adrenaline or cocaine), and by relaxing the plain muscle (amyl nitrite, benzyl benzoate, papaverine). The drugs could be administered by injection (atropine, hyoscine, adrenaline, papaverine, caffeine), by inhalation or spray (atropine, cocaine, adrenaline, nitrites, benzyl esters), asthma powders should be avoided, for the smoke tended to set up bronchitis, and by mouth (atropine, belladonna, etc., benzyl benzoate). It had been shown that pituitary extract constricted capillaries, and whilst its action on plain muscle would appear to contraindicate its use,

experience showed that some patients derived greater benefit from a mixture of pituitary extract and adrenalin than from adrenalin alone. The interactions of adrenalin, pituitary extract, and histamine-like substances on the capillaries were very complex, and then knowledge was still far from complete, but he suggested that the action of pituitary extract on the capillaries in preventing turgescence of the mucosa was of some importance. It should be given only in the attack in order to abort it, the effects were less when once the attack had become well established—that is when turgescence was well developed. In this connection it should be pointed out that a mixture of adrenalin and pituitary extract did not keep well. When combined in ampoules the activity fell off considerably in the course of a few months. The drugs should be given separately. Probably of all remedies the most valuable was a hypodermic of adrenalin 1 to 2 minims with or without pituitum at the first onset of distress. Every endeavour should be made to improve the general nutrition and resistance of the patient. Ascenic was of value. Dirty occupations and windy localities where dust was abundant should be avoided if possible. In the matter of climate patients varied greatly, but in general mountain air was beneficial and a holiday in Switzerland might result in diminution of attacks for months. Oxygen therapy had advocates but it was doubtful if it had any direct effect on the disease. In patients with much lung changes in whom dyspnoea was readily produced oxygen inhalation was undoubtedly beneficial. They felt better for it, often for some hours. A period of inhalation after going to bed might aid sleep, and thus diminish stress and promote restoration of the body. Bromides were of value in many cases by diminishing the excitability and instability of the nervous system they conserved the resources of the sympathetic and the endocrine organs. Iodides and thyroid extract assisted in exalting the activity of the sympathetic. The chief meal should be taken in the middle of the day, a light meal only in the evening. Fatigue, especially in the latter part of the day, should be avoided. The respiratory tract as a whole should receive careful attention, and chest development exercises should be used to prevent deformity and check the development of emphysema. Bronchitis should be treated on the lines indicated above.

Dr. H. A. INGLIS (London) thought that Dr. Langdon Brown's paper marked the greatest advance in the study of asthma down to the present time. Asthma was, he believed, merely a symptom of vasomotor disturbance, and the main object of treatment should be to stabilize the vasomotor system. Various things, notably the smell of fresh paint, certain proteins, sudden changes of temperature, certain altitudes, climates and localities, had a specific effect in some cases in disturbing the equilibrium of the circulation, but these things were only side issues, and should not be allowed to obscure the main object of treatment. He was very pleased to hear Dr. Langdon Brown's remarks on the influence of the sympathetic and vagus nerves in the causation of asthma, because he was convinced that the solution of the "asthma" mystery would in the end come from an investigation of the action and interaction of the sympathetic and vagus nerves on the circulation. It was a big question, as it involved myofibrils, hypersensitiveness, the action of the endocrine glands, and, in fact, the action of every factor which was concerned in the proper working of the body mechanism. The vasomotor system was peculiarly and extraordinarily responsive to treatment of the sympathetic fibres running in the mucous membrane. The mucous membrane which he usually selected for treatment was that covering the nasal septum, but other areas could be utilized. He was supposed to advocate nasal catarrhization, but, as a matter of fact, he was of opinion that the ordinary catarrhization of the nose did much damage in many cases, and often seriously interfered with proper treatment subsequently. Guided by the sphygmomanometer one could, by gently touching certain spots of the mucous membrane with a galvano-cutaneous point, regulate the circulation and so put an end to asthmatic trouble in the majority of cases, provided there was no

history of nasal polyp. If nasal polypus cases could be eliminated, the successful results obtained by his method of treatment would exceed 80 per cent., however severe or long-standing the asthma might be. Polypus cases stood in a class by themselves and he was sure that they would never solve this asthma problem until they knew something of the etiology, pathology, and the significance of nasal polypus. He had evidence to show that nasal polypus was the result of an endocrine deficiency. At present he was forced to consider nasal polypus cases as outlaws. They were bound by none of the common rules of treatment, and it was not even known what effect simple drugs would have upon them. Some drugs such as aspirin, nitroglycerin, and oxygonethem, acted as violent poisons in most cases of asthma associated with nasal polypus, but, curiously, if such a case tolerated aspirin it no longer ranked as a polypus case, and the prognosis became hopeful. If the polypus were removed the asthma as a rule became worse, and still more intractable to treatment. An individual polypus or better still part of a polypus could in some cases be taken out with advantage, provided that it was done without producing any disturbance, but any extensive operation for the removal of polypus in an asthmatic subject was very apt to be followed by disastrous results as far as the asthma was concerned. If operators could save some of the many patients who came to him who had been made helpless asthmatic wrecks by nasal operations for the removal of polypus, they might possibly pause and think. The protein reaction tests were useful in finding out what things must be avoided, but as a means of treatment they were practically useless. Vaccines, autogenous and otherwise, in most cases were worse than useless. Their chief effect was in the end to reduce the patient's physiological resistance, and, as might be expected, this led to a greater instability of the vasomotor system and increased the asthmatic tendency. He constantly saw cases which had been made worse by months and months of protein tests and vaccine treatment, which could be and were relieved of their asthma in a short time by making the vasomotor system more stable. He could quote many cases to illustrate the various points he had raised but they would take up time needlessly. He would, however, like to mention one case which explained what he meant by asthma being merely a symptom of vasomotor disturbance, and was, he considered, interesting otherwise. Some years ago he saw a lady who stated that she had had asthma all her life, but during the last five years the asthma had alternated with other troubles. She had in turn severe headaches, copious running from the nose, asthma, and diarrhoea. She never had more than one trouble at a time, but was never free from one or another. Each lasted about two hours and she did not know in what order they would come. His explanation of the condition was that she had headache, vasomotor rhinitis, asthma, or diarrhoea, according to whether the turgescence occurred in the head, the nose, the bronchial tubes or the intestines. By treating her nasal mucous membrane he reduced the blood pressure 25 mm., and apparently stabilized her vasomotor system for when she came to see him again some weeks later her blood pressure had gone but 5 mm. only, and she stated that she had had no return of any of her troubles. She would remain free unless some circumstance again upset her vasomotor balance.

Dr. A. F. HURST (London) said that during the thirty years he had suffered from asthma he had learnt how to avoid it and how to treat it when it came, but he was still asthmatic. He believed that the authors who from time to time announced that they had discovered a cure for asthma had made this mistake: they had found how one exciting cause could be more or less successfully treated, but they had paid no attention to the essential underlying cause which must be faced still he regarded it as inevitable. The constitutional excessive irritability of that part of the vagal innervation which controlled the motor and secretory activity of the bronchus—the "asthma centre"—remained unaffected. The only cure of asthma was not to have it. The less frequently the centre was set into activity by chemical, reflex, and psychical stimuli the less explosive it became, but even after twenty years of complete freedom asthma might recur under unfavourable conditions. The

irritability of the centre was increased by the fatigue of each day, thus making asthma most common at night, and by the fatigue of succeeding days of strenuous activity, thus making it more frequent and severe as the time for a holiday approached. Consequently, in hours rest before dinner a complete rest from work each week end, and at least two holidays of not less than three weeks' duration every year would do much to damp the activity of the asthma centre. The ideal holiday was Switzerland in the winter. An asthmatic, who for weeks had scarcely been able to crawl from one room to another without panting, found himself after a couple of days able to ski, luge, and skate as well as any man of his age. He was, moreover, able to eat anything and to do anything with impunity, as the chemical and reflex causes of his asthma were only operative when his asthma centre was tired and irritable. On returning home he was likely to have three or four months of almost complete freedom before he gradually became fatigued and once more subject to asthma on exposure to the various exciting causes which operated in his case.

Dr Hurst had lived long enough to have passed through two waves of therapeutic enthusiasm. The arrival of Dr Alexander Francis from Queensland over twenty years ago seemed to promise a novel cure for all asthmatics. His treatment was helpful in many cases, but Dr Hurst was sure that neither this treatment nor any other intranasal treatment ever really did more than remove one reflex stimulus which could set the asthma centre into activity.

In 1919 Dr Hurst had visited Dr Chandler Walker at the Peter Bent Brigham Hospital in Boston and had been filled with enthusiasm for the prospects which his method of cutaneous tests for protein sensitization appeared to hold for the treatment of asthma. Dr Hurst was, he believed, the first to repeat this work in England, but he had regretfully come to the conclusion, after a prolonged trial, that it was of little if any practical value. He heard from many British physicians that their experience was identical using Walker's own proteins and those prepared by various English firms, and also the raw substrates themselves, he had hardly ever obtained a positive reaction in an adult except with pollen, and the pollen reaction had already been demonstrated by Freeman several years before the appearance of Walker's papers. There was of course, no doubt about the fact of toxic idiosyncrasies but a careful consideration of the history was of infinitely more use in recognizing their existence than the cutaneous reactions and with the exception of autogenous vaccination for chronic or recurrent nasal and bronchial infection specific immunization was rarely called for. Every case required a thorough investigation, as by this means alone was it possible to discover and deal with the various exciting causes peculiar to the individual, and to find out in what way the irritability of the asthma centre might be reduced.

Adrenaline

It was rare for the exciting causes to be so completely controlled that no further attacks of asthma occurred even when the individual was tired or otherwise abnormally susceptible. As nothing was more exhausting than frequent bouts of asthma with the loss of sleep to which they gave rise it was of the greatest importance to stop the retinal attacks as quickly and as completely as possible. Every asthmatic owed a debt of gratitude he could never repay to Dr Brian Melland of Altrincham, whose discovery in 1910 that adrenaline could stop an attack was the one great advance in the treatment of asthma since Sir John Flower wrote his monograph on the subject over two hundred years ago. Dr Hurst had developed the technique of the adrenaline treatment in his own case and in that of numerous patients who had come under his care, with the result that he believed it was quite unnecessary ever to have a bad night as a result of asthma. It was essential that the injection should be given directly the attack began during the night it should be given the moment the patient was sufficiently awake to realize that he required it. Adrenaline was the only drug administered subcutaneously which he always advised the patient to give himself, as otherwise it was impossible to inject it sufficiently promptly. If given without delay, the patient was often

asleep in less than five minutes from the moment he woke feeling dyspnoeic. Used in this way very small doses were sufficient. The speaker never gave himself more than 1 minim of 1 in 1,000 solution of adrenaline chloride, and he had rarely found a patient who required more than 3 minims, although in many instances he had been told by the patient's doctor that 5, 10, or 15 minims were needed or that adrenaline was entirely without effect. This was always due to the fact that it had not been injected until the attack was at its height. Under such conditions 15 minims might produce no other effect than tachycardia, tremor, and a feeling of collapse, whereas, given at the onset, 1 or 2 minims would have completely aborted the attack, without even producing any rise of blood pressure.

Status Asthmaticus

He had seen a few cases of status asthmaticus a condition in which the patient was in a state of continuous severe asthma, which lasted for many hours or even days in spite of the use of adrenaline and morphia, with the result that he became completely exhausted from want of sleep and the physical effort of forced respiration. Such attacks could always be stopped by the continuous injection of adrenaline. After injecting 3 minims the needle was kept in position. 1 minim was then injected every quarter of a minute until relief occurred. As many as 40, 50, or 60 minims might have to be given, but eventually the attack ceased and the patient fell asleep as the last injection was given. These enormous doses produced no unpleasant symptoms, although under ordinary conditions 5 minims injected in one dose might have produced tachycardia and considerable malaise as adrenaline was excreted so rapidly that no cumulative effect occurred, except curiously enough in relieving the asthma. When the attack was at last brought to a temporary conclusion, the patient should be moved without delay to some place where past experience had shown that he was likely to be free from asthma, as it was difficult to prevent repeated relapses after a very severe attack except by a change of environment.

Mr FRANK CORR (London) thought that he could make the best use of the few minutes at his disposal by somewhat dogmatically touching on a few practical points. Asthma was not a disease but only a symptom occurring in a great variety of complaints due to many totally different causes. The grosser symptoms were caused by a spasm of the bronchial muscle and a secretion from the mucous membrane. As both these could be made to occur in the lungs of a sensitized animal after their removal from the cause, the influence of the central nervous system was not essential, and should not form part of a definition of asthma. The majority of cases fell into more or less clearly defined types. There was the type sensitive to foreign proteins, the type due to overfeeding, or the wheel and type, types showing great seasonal variation, as hay asthma, a type which was always preceded by a cold, a periodic type, where the asthma reached its height, then diminished in severity before recurring again, the whole cycle taking a month or two to complete, an occupational type, where the patient after many years became sensitive to a protein with which he worked, bakers and millers being common examples. In another group of cases a rare type followed an acute bronchitis or some other bacterial invasion of the lungs, and was curable by an autogenous vaccine from the organisms present. The collagenolytic type was a clearly defined type of case which commenced with sneezing fits and, as the years passed, developed urticarial digestive disturbance and asthma. The patients were not found to be sensitive to anything, they bruised easily and were all of them fat, or at any rate well covered women. The first line of treatment then, consisted of tilting a very close history to discover what type of case was being dealt with. Next came the investigation of the dermal reactions. Every single case of asthma, no matter in what type it might be placed must be fully and properly tested to every protein with which the patient came in contact. In his book published two years ago he quoted statistics of 350 cases, claiming definite reactions in 52 per cent of cases. Although

exactly comparable to the figures of American workers, there had been considerable criticism of these figures. He had recently made out the statistics for a subsequent series of 500 consecutive cases of asthma, 58 per cent of these gave positive dermal reactions to one or more proteins. Thus, he considered it was due to the use of several rarer proteins not formerly in his possession and to which an occasional patient had responded. Cases of ordinary hay fever were, of course, excluded from both series but 12 cases of pure hay asthma occurred in the last series of 500. No less than 36 per cent of the first and 38 per cent of the second series gave a plus 3 or larger reaction. He did not suggest that every patient who gave a reaction would immediately be cured but he had cured dozens of cases with a plus 1 or even lesser reaction. He cited one case as an example. A patient from Newcastle aged 58 had had asthma for thirty-six years and gave a plus 1 reaction to goose feathers. He wrote to Mr. Cole eighteen months later saying that since he gave up his feather bed and pillows he had been entirely free from asthma. The general practitioner was handicapped, biased and perhaps disgusted with the skin reactions because the majority of test sets sold to him were completely valueless. Mr. Cole had had a small patient sent to him recently. The mother said the child had been fully tested in a university town in the North, no reactions had been obtained in spite of the fact that the mother had insisted that the child could not sit behind a horse without sneezing. The boy gave a plus 5 reaction to horse dander. Having found a reaction the method of avoidance must be most scrupulously undertaken. Cats, dogs, parrots, etc., must be given up and feather pillows replaced by paper substitutes. Alternatives could be found for most foods to which the patient was sensitive. He had tested a child a year ago who was covered with eczema and found her sensitive to wheat, eggs, and cow's milk. The child had not touched these foods for a year, and the eczema had gone. The better educated the parent the more easily were these children fed by alternative methods. Three classes of proteins could not be avoided—horse dander (especially in large cities), pollen, and those proteins causing the occupational asthma. For these, desensitization by small doses must be used. Skin reactions were taken with dilutions of the protein each one being ten times weaker than the other until a dilution was reached which gave no reaction. Treatment was commenced with this dilution and the dosage very gradually increased. He had also used this method successfully by giving minute quantities by the mouth with certain foods and in that pernicious type of asthmatic sensitive to ispirin. But to dispense ispirin in 1/100 grain pills required great accuracy and was expensive. Passing to methods of non specific desensitization, he did not think that the horse asthmatic was an individual needing a protection against horse dander any more than he could imagine a person being sent into the world with his equipment perfect except that he was minus a protection to cravat or face powder, or that during life he somehow mislaid his protection to Brazil nuts. Sensitization was something added to an individual, not something lost. But it was no less difficult to see how to manufacture what he called specific adzymes to these many different proteins of such an exact counterpart and such extraordinary specificity that they could distinguish between the proteins of a hen's egg and that of a duck. Lumiere suggested, however, that if we could split up these proteins into their component parts, a very few basic radicals would be necessary. Ten such would allow something like thirty-six million different combinations. If they looked round for something comparable to this in nature, he suggested that they could find it immediately in the sense of smell. What was the olfactory organ but the most perfect analytical chemical laboratory? The smell of an orange was always the smell of an orange and nothing else, that was absolutely specific. In the same book Lumiere proved, Mr. Cole thought very conclusively, that acute experimental anaphylaxis was due to a flocculation of the colloidal particles of the blood. This was caused by the specific adzyme reacting with fish protein to which the animal was sensitive and a precipitate forming. What practical indications for treatment could be deduced from these facts and

therein? They could by minute doses of the protein to which the patient was sensitive, use up this specific adzyme without at any time giving a dose large enough to cause fresh formation of the adzyme or just as the judges thought to nullify the foul smell of prisoners by the use of mosquitos, so they could remove the specific adzyme by superimposing another protein on to it. Practically any protein would do for this purpose, mill and horse serum had been largely used, due care being taken that the patient was not sensitive to the one selected. A bacterial protein such as the mixed coliform vaccine the method of Danysz was excellent for many cases. If they were to imagine that a specific adzyme had a composite structure like a telephone number, smaller compounds than full proteins such as the proteoses and peptones would serve to alter the specific adzyme beyond effectiveness, just as the smallest alteration at the telephone exchange would give a 'wrong number'. Hence possibly the value of the various peptone injections. Here there was also a considerable scope for trial of other protein fractions such as a protein from which the Vaughan's split protein the poison group, had been removed. Similarly different proteins and so also their specific adzymes being made up of different rings one form of injection might have a far greater nullifying effect when superimposed on a patient sensitive to one protein than on another case sensitive to another protein. They found that the results obtained with the same injection in apparently similar forms of asthma varied considerably. Another variation of this was the method of auto-hemotherapy—extracting blood from a vein and reinjecting it again subcutaneously before it had clotted. Here there could be no possibility of causing any anaphylactic symptom but the blood altered as it clotted and so perhaps became a mild foreign protein which, however, they could use in very much larger quantities than in other cases. In the case of a child who only got asthma with a cold but caught colds very frequently the dermal reactions must be tested, especially that for feathers. When the nose, throat, and lungs were raw with a cold feather proteins would press through but they would not do this at other times. Removal of the feathers would stop the asthma, but not the colds. Two things were required in catching a cold—a chill, or some lowering of resistance, and some micro organism. This was happily a rare combination for most people. If however, the patient carried his own organism, he would have a cold every time he became chilled. Search for the focus of these colds must be made, and in children, in nine cases out of ten this would be found in the tonsils. Nothing gave such good results in curing asthma as their emulsion. Failing the history of foods from patient after patient it was surprising how very consistent were their answers to questions. Pastry, cheese, heavy puddings, thick soups, were the foods they especially avoided, bearing out exactly the excellent dietary of Dr. Adams of Glasgow. Protein, starches and fats required entirely separate digestion by different enzymes for each. Therefore, starches cooked in fat as in the case of fried potatoes, suet or milk puddings, proteins in fat as cheese or all three as in nuts, must be completely excluded from the diet. In certain cases he added one day's starvation a week. He had many patients who had been free from asthma for many years and yet returned this diet continually because they appreciated the immunity it gave them. In conclusion he emphasized the great importance he attached to the dermal reactions and added that in their present state of ignorance when they did not know the mechanism of the sense of smell when the colloidal condition of the blood serum was not mentioned in the most recent work on haematology, when a biochemical explanation of the action of potassium iodide was difficult when they were rather doubtful as to what happened during a common cold or why corns ached when it was going to rain it was best not to call the asthmatic a neurotic, because he told them something they did not understand.

The Rev. Dr. BRIDGES (Greenwich) thanked Dr. Langdon Brown for his able paper, and said that inhalant therapy in the most distressing complaint had not had a fair chance. No doubt this was due, he thought, to the want of a proper inhalant apparatus. Most of the hand inhalers

or atomizers were unsatisfactory and very uncertain in their action, inasmuch as they did not regulate the dose of the drug used, gave no continuous stream of vapour, and did not convey the vapour to sufficient depth to reach the diseased parts. Oxygen inhalations had given good results, but usually these types of apparatus did not vaporize drugs. Lately he had come across an apparatus which was attached to an oxygen cylinder, through which valuable antisthmatic drugs, such as adrenaline, and a new proprietary remedy named apnoegene, had proved of great service in cutting down in a few minutes an attack of asthma. This apnoegene contained a synthetic preparation of adrenaline 1 in 1,000 and 1 per cent anæsthetic. He believed that this apparatus could be seen at the exhibition, it vaporized any liquid drug, and the dosage was regulated by a gauge showing the rate of the flow of oxygen. The vapour was extremely fine and of equal density throughout the administration of the dose, lasting from fifteen to twenty minutes. He spoke very highly of an inhalant mixture he himself had prepared, composed of oleum cypripati, oleum cinnamonomi, and camphor in liquid paraffin. He considered inhalant therapy more beneficial to the patient psychologically than injection therapy, particularly in cases of asthma, which had so considerable a nervous element in them.

A member said he had not intended to take part in this discussion, but having heard suggestions that the subject of true spasmodic asthma could not be permanently cured if his susceptibility to attack he would like to contribute a personal note. It must not be forgotten that asthma, in the great majority of cases, if not in all, was one of the well known symptom triad of inherited gout and in treatment due regard must be paid to this constitutional predisposition as well as to the immediate psychic or protein excitant. His own family history illustrated every phase and factor mentioned. In his own case it was two series of attacks every five or six days without a break, of true spasmodic asthma. Recovery from the effects of one attack appeared to be the signal for another. Permanent cure was effected over twenty five years ago by a variant of the method, but doubtless including the same physiological process as that mentioned by Mr. Frank Cole. The process of auto-therapy in his own case was effected by hydro-therapy and counter irritation prolonged over a sufficient period of time, and analogous to the series of peptone—on specific injections of Mr. Cole—which was the greatest advance in the treatment of this disabling affection. But for the results to be permanent due regard must be paid to every activity of daily life in relation to the constitutional diathesis. Thus every asthmatic might be given the hope of cure, so far as the attacks were concerned, and of relief, therefore, of the organic changes which resulted from long duration of the affliction.

The President spoke of the relation between eczema and asthma. Asthma might alternate with dermatitis in the same patient. He described a case of chronic eczema which, when cured, developed severe attacks of asthma. He thought that this connexion was more than a coincidence. Irritation of the skin might relieve irritation of the bronchi.

Dr. LONDON BROWN in reply thanked the speakers for their remarks. Many points had been raised during the discussion. In reply to Dr. Poulton, he thought that bronchial glands might act by damming up the secretions and this would lead to auto sensitization. Attacks might be relieved by preventing reflex irritation from the nose. For this purpose he used atropine, eucalyptol, and anæsthetic made up with paraffin. He approved of the term "allergy" which Dr. Poulton had introduced and agreed that fasting would relieve asthmatic attacks. Some of the speakers had misunderstood what he had said about oxygen treatment. He thought that exploitation was a fair term to use in criticizing the method as applied by certain people outside the profession. He wished to insist that no stigma attached to emotion or to psychic phenomena. He thought that skin tests had a general rather than a specific application. In reply to Dr. Hamill he thought that the value of amyl nitrite was somewhat uncertain, piperazine some-

times had good effect. The action of caffeine was probably due to stimulation of the higher centres, and with them of the sympathetic system. Cocaine also stimulated the sympathetic. He agreed with Dr. Hamill that the use of powders was undesirable. He thought that Dr. Francis's method of light cauterization had proved of great benefit. Dr. Hunt's experience had been of great value in the discussion. Dr. Hunt, like the poet, had learnt in suffering what he taught in song. He was much interested in Mr. Cole's treatment by auto-hæmotherapy. With regard to the relation between asthma and eczema, he gave the pedigree of a family where asthma and eczema had alternated in the different generations.

SECTION OF OPHTHALMOLOGY.

W. MURDOX BEAUMONT, M.R.C.S., President

PRESIDENT'S OPENING REMARKS

It has been decreed, happily for me, and still more happily for you, that no introductory address shall be given. This decision, however, does not preclude me from expressing the very great pleasure it gives me to welcome you very warmly to this

terraced hillside town
Where healing streamlets run
Still sparkling with their old renown,
'The Waters of the Sun.'

This reference to Bath especially appeals to us to-day because we are honoured by the presence of American guests. The lines which I have quoted were written by an American citizen who visited and loved our Queen City of the West. He was both a distinguished member of our profession and a great and genial poet. I need hardly say that I refer to Oliver Wendell Holmes. As one of 29,000 members of the British Medical Association I hold out the hand of fellowship to the representatives of the 90,000 members of the great American Medical Association. We rejoice to see them here to-day, and we offer them all the amenities which Bath can supply. Ladies and gentlemen, members of our American and British Ophthalmological Societies, I would remind you that our old city has had two glorious epochs before the present one. First, the Imperial era, illustrated by the Roman Bath. Coming down the centuries we arrive at the Renaissance in the eighteenth century, illustrated by the Royal Crescent, one of the finest specimens of residential architecture of modern times. You will not forget to see the Roman Bath, the touchmark of the Imperial epoch, but do not omit to visit the Crescent, the touchmark of the Royal epoch.

DISCUSSION ON EYE INJURIES AND INTERSTITIAL KERATITIS

OPENING PAPERS

I—W. T. HOLMES SPICER, F.R.C.S.,
Ophthalmic Surgeon and Lecturer on Ophthalmic Surgery to
St. Bartholomew's Hospital, Consulting Surgeon to
the Royal London Ophthalmic Hospital.

In a certain number of cases of interstitial keratitis the attack is said to have been caused by an injury, but frequently there is a close association between the injury and the disease. This association, if it could be established, would be of great importance in view of claims for insurance and workmen's compensation. The injury is often trivial—a foreign body on the corner, a splint from a railway engine or emery wheel in abrasion by a finger-nail or blade of glass. In all of these cases there is a breach of surface. In others, such as a blow by a fist or potato, there is no external wound. In another case there is a chemical injury to the eye from caustic potash, other attacks follow directly after carefully planned and well executed surgical operations on the eye. A typical case is that of a man grinding a tool, who got a spark of emery into his eye, it was removed after a short delay—a very common occurrence

having no after effects. In this case, however, the eye remained irritable, bloodshot, and intolerant of light for several weeks and gradually passed into a typical attack of interstitial keratitis, followed by a similar attack in the other eye. The patient bore the stigma of congenital syphilis which made it easier to determine the cause, but the stigma may be absent, and the ordinary person without knowledge of interstitial keratitis could not be blamed for regarding the keratitis as the direct result of the injury.

In 5 per cent. of the cases there is a direct association with injury—that is, the injury is seen to pass into interstitial keratitis while the patient is under observation. This percentage is in agreement with those of foreign observers and more recently with those of Cunningham.

Harrison Butler, from an examination of his records, gives a much higher percentage. He finds that at least 20 per cent. of the cases of interstitial keratitis are preceded by an injury. In a paper which he read recently before the Society of Medical Officers of Health, which he has kindly allowed me to see, he comes to the conclusion that an attack of interstitial keratitis may be precipitated by an accident to a corner predisposed to it by syphilis or tubercle, that a very slight trauma like the instillation of drops or a general anesthetic is enough in a corner, that the attack may follow in the other eye, that the injury may directly precipitate interstitial keratitis in the second eye without participation of the injured eye, and he asks whether some trauma is not always present before the attack. My percentages were taken from cases of injury to the eye which were watched and seen to pass into interstitial keratitis; the percentages would have been higher if the histories had been diligently inquired into. If every deviation from the normal and every injury to a remote part of the body is to be considered as a cause of interstitial keratitis, it will be possible to rope in a very large number of cases. But histories are fallacious; the patient is nervous and often honestly so, to provide what is needed in the way of history; it gives an explanation to his mind and relieves him of the unpleasant thought that there may be something constitutionally wrong with him. For this reason the nature and severity of the injury, the interval between it and the attack must be carefully investigated. Injuries to eyes occur daily in large numbers, especially in manufacturing towns, but the number of such cases followed by interstitial keratitis is quite small. When interstitial keratitis occurs, the injury is often very trivial, such as would be quite incapable of having any after consequences in healthy eyes; it always takes on characteristic features, and the patients generally bear on their bodies the peculiar marks of congenital syphilis. Then there is the further difficulty of explaining the attack in the other eye which commonly occurs.

The ordinary man has heard of sympathetic ophthalmia in which an injury to one eye is followed by serious inflammation in the other, leading often to complete blindness in both; the broad features of the two occurrences are enough alike to satisfy him. But the characters of the two diseases are entirely different in every stage of their course, no one with any knowledge of diseases of the eye could mistake one for the other.

It is not possible to give a satisfactory explanation of the upper race of interstitial keratitis in the second eye in those cases in which an injury is assumed to be the cause of the attack. But if injury be not the direct cause of interstitial keratitis, the explanation of the association between the two eyes is not difficult. A large number of those infected with congenital syphilis have the stigma of the disease upon them, in the shape and size of the teeth, the aspect of the face, the shape of the bones, and the like; those people are almost certain to suffer from interstitial keratitis some time in their lives. It is rare to find these stigmata in adults without finding traces of old interstitial keratitis in their corneae, whenever I have met a person of middle age with the characteristic features, I have, so far as I have been able, examined the cornea and have never failed to find the traces of past interstitial inflammation.

Some instructive cases bearing on this may be described

There are notes of several successive operations for congenital cataract in persons who bore all the marks of congenital syphilis, but in whom no interstitial keratitis occurred. There are notes of two cases of lamellar cataract occurring in one person which underwent successful operation. In one eye three needlings were performed, and in the other a needling was followed by cataract extraction, and in iridectomy for subsequent prolapse of the iris. Both eyes in a normal condition had no vision; they remained quiet for four years, then interstitial keratitis of severe gummatous kind followed—that is, repeated severe injuries such as the operations here did not cause interstitial keratitis, although all the conditions favorable to its occurrence appeared to be present. The protracted had not reached the required degree of maturity or evolution, but it did so spontaneously a few years later. On the other hand, in two eyes in different people, a simple first needling was immediately followed by severe interstitial keratitis, which was very alarming, but it matured was not it but unexpected. There are also many notes of cases in which no apparent deviation from health or exposure to weather or cold, or privation brought on attacks, and on the other hand there are notes in which serious diseases occurred in people showing the stigma of congenital syphilis, without starting the disease in the eye.

The conclusion seems inevitable. The interstitial keratitis depends on the presence in the eye of the organism of syphilis, the *Spirochaeta pallida*, and on its readiness for evolution; if that organism be present interstitial keratitis is practically certain to occur at some time. If the organism be present but the required state of evolution be not reached, there will be no attack. If the required state be not reached in the two eyes simultaneously there will be an interval between the two eyes in the occurrence of the condition. If the state of evolution has been reached there will be an attack in the absence of any stimulus, and in spite of anything that can be done.

This is in agreement with the occurrence of syphilitic manifestations in the body generally. There is the period of acute mitis in syphilitic infants, the period of affections of the choroid and retina, the mingled attacks, the skin eruptions, the bone diseases, the gumma, and the nerve degeneration; they cannot be hurried or brought on out of their proper sequence, and on the other hand, even with the present means of treatment at our disposal, they cannot be completely suppressed.

The inevitable occurrence of interstitial keratitis in the presence of the spirochaete does not exclude the possibility that in injury and an attack of interstitial keratitis may be a coincidence. We do not know how long the spirochaete can remain in a state of readiness for evolution without starting the attack. It is possible that the very slightest event, deviation from health or injury may determine the onset, the longer the period of readiness for evolution the greater is the possibility of the coincidence between an injury and an attack. If the injury were in every eye a coincidence and had no part in the attack we ought to find cases in which an injury to one eye has been followed by interstitial keratitis in the other.

I have no doubt this has occurred, but I have no record of such an occurrence. The effect of an injury on the tissues was described long ago by Pagen in his clinical lectures, when he said that the effect of an injury or operation or general disturbance of nutrition on a put was to bring out any latent constitutional tendency. He cites among other cases that of a man who bore his forearm, and within five minutes had a sharp attack of gout in the hand, and another case in which a well marked syphilitic eruption appeared in a man in whom no syphilitic symptoms had been observed for years, a day or two after a fight at seeing the death of a friend.

If we are called upon to give an opinion in a case where an attack of interstitial keratitis follows shortly after an injury, what is our duty? If the characteristic signs of interstitial keratitis are present, it is our duty to point out that the patient shows the signs of congenital syphilis. These signs are the Hutchinson teeth, the facial aspect, the shape of the bones of the skull, the high vaulted palate.

the periosteal nodes, Clutton's joints, nerve deafness, a positive Wassermann reaction, and a specific family history. The presence of these signs indicates that he is suffering from congenital syphilis, and that the interstitial keratitis is a manifestation of congenital syphilis; this keratitis is certain to appear at some time of life, which depends on the degree of evolution to which the *Spirochaeta pallida* has reached. If he has not the signs of congenital syphilis upon him, and if the attack in the eye is a typical one, it is equally certain that the attack in the eye is syphilitic. I believe that typical interstitial keratitis is always syphilitic. The injury would not have given rise to the involvement of the eye unless the spirochete was present in the tissues of the eye, and had reached the stage of evolution or readiness necessary for the outbreak of the attack.

It seems impossible otherwise to explain the occurrence of the disease in the second eye.

II—W. B. INGLIS POLLOCK, F.R.F.P.S.,

Surgeon to the Glasgow Eye Infirmary.

INTERSTITIAL keratitis is an inflammation of the middle and deeper layers of the cornea. It may commence at the centre of the cornea or towards the margin. When it commences at the centre it commences as small grey spots or maculae. As the spots increase in size they coalesce and spread towards the periphery. Between the different centres there may be a diffuse cloudiness. Where the disease develops from the periphery, the cornea looks grey and loses its lustre at the edge.

With a magnifying glass it can be seen that the spots are made up of separate maculae. As the disease spreads the spots increase in size and coalesce until they have covered the entire cornea. Vascularization rapidly develops, and at a certain stage the cornea appears to have a salmon tint. When the disease has reached its head the whole cornea becomes opaque, and the iris cannot be seen through it, the sight becomes so dim that the patient is only able to count fingers if they are held up before the eye. Pathologically it is found that the main lesion is a lymphocytic and vascular infiltration limited to the middle and deeper layers of the cornea.

SYMPTOMS

Interstitial keratitis is accompanied by photophobia and lacrimation. Upon examination it will be observed that there is no purulent discharge from the eye and on separation of the lids it will be seen that there is a circumferential congestion, a pink blush around the margin of the cornea. At the height of the attack the cornea has lost its lustre, although there is no distortion of the reflection of a window when this is looked for, because there is no lesion of the anterior surface of the cornea. As the condition improves the window reflex recovers its clearness, showing that the disease has been entirely under the surface of the cornea, there is always more or less mist.

Both of my cases following eye injuries began as simple traumatic ulcers, which commenced to clear up under the usual remedies, but by the tenth or fourteenth day were seen to have become worse. One patient was aged 18, and the other 22. The Wassermann reaction was found to be strongly positive. Treatment by stabilisation was commenced at the time when the blood was taken for the Wassermann test and resulted in nearly complete clearance of the first eye within a few months, while the second eye became slightly implicated, but cleared completely.

DIAGNOSIS

On examination of cases of keratitis interstitialis and indeed of all external diseases of the eye it is important to place a patient before a good light from a window so that the reflection made by the window can be observed on the cornea.

If inflammation is present in the middle and deeper layers of the cornea, such as in keratitis interstitialis, then the reflected image of the window will be perfectly clear and not distorted, as in the normal eye but in the acute stage it will be dimmed. Tuberculous interstitial keratitis may simulate syphilitic in all respects and be extremely difficult to diagnose. This variety of conjunctivitis accom-

panied by the formation of phlyctenules on the surface of the cornea and the limbus just outside the corneal margin may be mistaken for interstitial keratitis. It will be noticed, however, that the vascular infiltration is only conjunctival, and that there is no deep circumferential congestion, as in keratitis interstitialis.

A great deal of work has been done in France recently on examination with the slit lamp and binocular microscope, and shows the inflammation distinctly limited to the middle and deeper layers of the cornea, with the presence of deposits on the posterior surface of the cornea and sometimes on the anterior surface of the iris. Attempts have been made to diagnose the disease by the slit lamp, but it has not yet been possible to distinguish with certainty tuberculous and syphilitic cases.

In former times great stress was laid on Hutchinson's triad: keratitis interstitialis, the characteristic peg-shaped teeth, and the nodes on the tibia. Other writers have laid stress on the presence of osseous and rhagades.

The Wassermann test should be performed in every case. It is the only certain method of distinguishing these two affections although it must be always remembered that both may be present simultaneously.

TREATMENT

The treatment of syphilitic interstitial keratitis has for many years been carried out by the use of mercury administered either by injection or internally. It was not until I saw the results of Lees's work in Edinburgh that I realized what could be done by the administration of arsenical compounds. Since that demonstration I have put all my cases under the venereal specialists for treatment by modern methods. They use stabilisation, giving 0.015 gram intravenously. If neosalvarsan or novarsenobillon is employed and a portion escapes under the subcutaneous tissues it sets up more or less troublesome irritation. Stabilisation does not give any trouble if it escapes into the tissues from the vein and it seems to be tolerated very well by almost all the cases I have had under my care. The dose is repeated weekly for eight or ten weeks and is accompanied by the administration of mercury, hydriargyrum cicutæ, ferri et potassii tartarus, and milk sugar, 1 grain of each once daily, or the mercury can be given by injection. My usual practice is to ask for the blood to be taken immediately I have made my diagnosis and to have an injection given at the same time, after the blood is taken if possible. This is to save time, because if the treatment is commenced at once it is possible to save the disease from occurring in the second eye, and to prevent blindness of the first eye.

If both eyes are implicated, then the treatment must be commenced at once, because the longer it is left the more destructive have been the processes on the cornea, and consequently the denser the opacity left on the cornea. The rapidity with which the disease may advance shows that the treatment is urgent if blindness is to be prevented.

After a course of treatment such as indicated above, one may omit the treatment for a month, and then commence a second course. During the interim, the mercury and iron may be omitted, and the child put on milk, cod liver oil and syrupus ferri iodidi, some surgeons give in addition, thyroid extract 1 or 2 grains, if necessary.

The course should be repeated as long as there is any improvement in the cornea even after the blood becomes negative, and only when the opacity persists in spite of all treatment can one consider the question of stopping the courses. I am certain that by efficient treatment it is possible in certain cases to prevent the implication of the second eye.

Sometimes the courses have been substituted by silver salvarsan, this has been tried and recommended by Colonel Harrison, and it seems to do very well.

While the patient is under treatment with these drugs it is most important to watch continuously for the onset of jaundice. The venereal specialist to the Glasgow Eye Infirmary, Dr. Pinrose, has suggested that the child should be given sulphur with cream of tartar and treacle, a dessertspoonful twice a week. If jaundice supervenes the patient should be given intravenous or contraindicated. The

kidneys must also be watched and the urine tested regularly to see that no damage is being done there, in which case it is necessary to stop the treatment at once.

For local treatment I give atropine with diosmine 2 per cent and vasoline, and also belladonna lotion. The diosmine helps to clear the opacity in the cornea, and the atropine to relieve the iritis which always accompanies the condition, the sooner the pupils are dilated the sooner the inflammation and redness subside in the eye.

Tuberculous Cases.—For these cases I give injections of tuberculin 150 000 mg. for three weeks, then increase it to 1/25 000 for three weeks and up to 1/20 000 and 1/10 000. In cases where there is tuberculous infection with syphilitic basis the combined treatment is necessary. In cases where there are septic teeth removal of these is necessary and the internal treatment should be mercury, cod liver oil and iron.

Since modern methods have been employed the end results are much more hopeful than in the old days when mercury alone was used.

Note.—The substance of the report was communicated to a meeting of the Association of Ophthalmologists.

GENERAL DISCUSSION

Mr. A. LEITCH LEECH (Glasgow) said that in an examination as to the causes of blindness in some twelve hundred persons he had found that a fair number of cases of blindness resulted from the failure of cataract operations. Such cases were due either to sepsis from want of adequate aseptic precautions or to inflammation of some part of the visual tract. In these latter he had frequently found that the Wassermann reaction was positive. Was the disaster due to the trauma plus the presence of syphilis? He believed that it was—a conclusion which seemed to support the views which Mr. Holmes Spicer had expressed.

Mr. N. BRISTOL HARRIS (London) said all would agree with Mr. Holmes Spicer's statement. "The injury would not have given rise to the involvement of the eye unless the spirochaete was present" and so on. But could it be said that the attack would have occurred at the time it did occur, trauma or no trauma? On that turned the medico-legal issue. He did not think there was sufficient evidence, but it was needed before they could be sure of their ground in claiming that the eye manifestation was inevitable at a given date. He suggested that the allegation of injury needed investigation. He saw many school children who were blind from syphilis. It was remarkable how rarely parents alleged injury as a cause. Interstitial keratitis was attributed to a cold in the eye, but choroiditis never had an alleged cause. He wondered if the allegation by workmen of injury as the precursor of interstitial keratitis was always justified. It seemed possible that the common initial symptom of ocular inflammation as the feeling of "something in the eye" was responsible for the allegation of trauma.

Mr. C. H. WALKER (Bristol) commented on the fact that judged by an investigation of the records of ophthalmic clinics in Bristol thirty years ago, interstitial keratitis was often of frequent occurrence—severe, atypical, and untreatable. He had seen two cases which quite definitely seemed to be the result of trauma, and one which followed acute conjunctivitis in one eye. In each of these cases the keratitis was moderately severe, quite typical, and was only present in the eye which had been affected by the injury or inflammation. He could not say that he had ever seen interstitial keratitis in one eye as the result of injury in the other eye.

Dr. L. J. PRINCE (Glasgow) had seen a great number of cases of interstitial keratitis, both in children and adults. The diagnosis was mostly not in doubt. The Wassermann reaction was ascertained in almost all cases, in most it was positive in some, especially in adult, it was negative. Where the evidence of syphilis was clear it was important to disregard a negative Wassermann reaction and to proceed with the appropriate treatment. As to cases occurring

after trauma, sometimes the mother gave a definite report of this. He had examined such histories with great care, and had never found one in which the condition began in the eye not injured. Were it due merely to coincidence one would expect it to happen as often in the uninjured as in the injured eye. As regards the pathology, it must be remembered that it was generally accepted that the strain of the oil was as important as that of the mydriatic organism, and in the cases they had in the fact of trauma a disturbance of the seal. In many cases it was easy to distinguish between tubercle and syphilis but in not a few it was very difficult, and the diagnosis of syphilis was reached only after a period during which antituberculous measures were more or less ineffectual. On the other hand, cases definitely syphilitic were sometimes found in which any further treatment with antisyphilitic remedies seemed inadvisable and tuberculin did much good. In such a difficult case treatment by the most powerful weapons, such as the diosmine substitute, was to be used and pushed, sufficient dosage in the hands of one who was prepared to deal with any untoward effects must be begun without delay.

Dr. WALTER HENRY (Toronto) referred to a case of interstitial keratitis coming on in both eyes within ten days after an injury to one eye.

Dr. M. SCHWARTZ (Philadelphia) had not analysed his cases of interstitial keratitis with respect to injury and could not add anything from the clinical or statistical aspect of the subject. He thought it quite possible that a corneal injury, even a slight one, in a subject of inherited syphilis might assist a successful attack of *Spirochaeta pallida* on this susceptible tissue by lowering the resistance of the cornea. Such an injury might be regarded as an influence hastening the corneal disease, which without it, however, was practically sure to occur. It seemed to be analogous to the effect of injury in a tissue which, because of its failure to resist a bacterial attack from an area of local sepsis (focal infection) which previously had been ineffectual—for instance, an iridocyclitis following excessive strain on the ciliary muscle in a patient with dental sepsis.

Dr. R. KERRY (Montreal) said that if one excepted certain cases of infected suppurative lesions, he thought that all inflammations of the eye must be regarded as secondary. He had generally considered cases of interstitial keratitis to be either syphilitic or tuberculous, when the former was the case no benefit followed the use of iodine, but in the latter contingency the disease cleared up promptly, so that there was thus provided a rough and ready therapeutic test.

VISUAL HALLUCINATIONS IN SANE PEOPLE

BY

ARTHUR W. ORMOND, C.B.E., F.R.C.S.,
Ophthalmic Surgeon and Lecturer in Ophthalmology, Guy's Hospital.

I venture to bring to your notice to-day the subject of visual hallucinations in sane people, hoping to hear from you your own experience and the experience of others that you know concerning this very interesting subject. Some years ago I was asked by an old woman who came to see me in the out-patient department at Guy's Hospital, whether I could do anything for her with reference to the "faces" which used so frequently to annoy her. She saw them she said, silhouetted against a white counterpane or sometimes against the sky, as they peered in at her through the window and made grotesque grimaces at her, which in the first instance were not unpleasant but merely comical but later became revolting, and were of considerable annoyance to her. She was quite aware that they were not real, but only appearances, still they were unpleasant and disturbing. My attention was directed to the subject by the late Sir Anderson Crichton, who recounted to me one evening the history of a patient of his who had written asking him to be good enough, when in the neighbourhood of his home to call and see him. After a short talk the old gentleman suggested that they should retire to another room, where, having carefully

locked the door, he described to Sir Anderson the appearances which he saw and which were somewhat similar to those of my patient and inquired if they foreshadowed the onset of my definite mental trouble. In addition I received quite recently a very carefully written statement of certain phenomena experienced by a medical man who had consulted me about his eyesight, and I will read you his account of his troubles.

On March 17th while drying my clothes after my bath I suddenly felt there was something wrong with my sight. I did not see fully but I seemed to see less. At breakfast I began to realize more what was amiss for I could not see my fork when using it. I immediately tested my field of vision and found that the left area was quite blind. This blind area started from a vertical line immediately in front of me. I had no headache nor other abnormal symptoms. After breakfast I went out—on crossing the road I felt rather nervous owing to the new eye trouble. On coming out of a shop I pulled open the right hand door without seeing that someone was holding open the left hand door for me. On my way home I passed a friend without seeing her as she was walking on the left. When I returned home I sat down and tried to read but had to stop as I felt sick and had a severe pain across my frontal and right temporal regions.

Little later I vomited twice when the feeling of nausea left me. My headache increased however so I went to bed. For three days I had complete loss of appetite. I only took liquid food the second day of attack. March 18th Dr. W. saw me. He noted I had no temperature and that my blood pressure was 135. He suggested a slight hemorrhage in the region of the chiasm. I remained in bed until March 23rd my urine (specific gravity 1015) was free from albumin.

On Tuesday March 23rd there was some improvement of the left field of vision and on the following day it became normal and has remained so up to now (April 5th). My sight however has altered since the attack and my glasses are no longer sufficient for reading. I wish to note certain peculiar phenomena that occurred during the period of hemianopia.

1. In recurring periods I saw very distinctly numerical figures appearing on the ceiling and walls in front of me. Generally two numerical figures appeared in well defined black characters—for example 71 22—all parts of the numerical figures were equal and flat on the surface. These numbers kept changing and moving. I think they appeared more to the left than the right.

2. As a variation I saw what appeared to be half words in handwriting characters and I found myself guessing the missing part. I remember one word or part word particularly and I guessed this to be attrition. There were many other half words but I cannot now recall them but they were very distinct and their character was peculiar inasmuch as the lower parts of the letters were bowed and quite unlike my own handwriting. All letters had this peculiar characteristic of bowing below. All the half words were hand written not printed thus differing from the numerals which appeared to be in printed characters and in black.

3. There was another curious phenomenon—the appearance of queer faces moving in a sort of procession always from right to left. They were queer comical faces for the most part and the side on the right of the picture twisted in a peculiar way—a sort of contraction from below upwards which included the lower part. The general effect was comical rather than repulsive. These phenomena appeared with my eyes open but the faces were seen with open and shut eyes. I might add that previous to this attack I have seen with closed eyes on occasions these facial processions when half dozing before getting off to sleep and have remarked to my wife about it at the time.

4. There was also a fourth phenomenon seen only with my eyes closed—a crimson area with an ever moving pattern like a kaleidoscope. The effect was that of fluid in motion with the patterns in black lines. I had headache of a neuralgic character all through the attack. This is now slight only. I never had a similar attack before.

N.B.—As a possible contributing cause I might mention that the day before the attack I was chopping up a wooden box very close to a fire. I felt the strain of the exertion and the heat rather much. I felt well however later and also the next morning immediately before the onset of the attack.

With regard to Dr. V.'s ocular condition I had seen him on several occasions, and he had full vision on each side with correction but had myopic astigmatism and when I saw him twelve months after the attack which he has related in his letter I found his condition much the same. There was no albuminuria and his Wassermann reaction was negative. I think that in all probability he had in attack of "migraine" which was unusual in lasting so long a time, but I would remind you here that in 1913 I published some notes of patients suffering from hemianopia following migraine who still remain permanently hemianopic.

Mackenzie in his book on diseases of the eye published in 1854 (p. 973) recounts the case of Nicol, the Berlin book seller who for nearly two months was constantly affected with special illusions.

Though at the time says he "I enjoyed a rather good state of health both in body and mind and had become so very familiar with these phantasms that at last they did not excite the least disagreeable emotion but on the contrary afforded me frequent subjects for amusement and mirth yet as the disorder sensibly increased and the figures appeared to me for whole days together and even during the night if I happened to wake I had recourse to several medicines and was at last again obliged to have recourse to the application of leeches to the anus. The operation on April 20th at 11 o'clock in the forenoon I was alone with the surgeon but during the operation the room swarmed with human forms of every description which crowded fast one on another. This continued till half past 4 o'clock exactly the time when the digestion commences. I then observed that the figures began to move more slowly soon afterwards the colours became gradually paler every seven minutes they lost more and more of their intensity without any alteration in the distinct figure of the apparitions. At about half past 6 o'clock all the figures were entirely white and moved very little yet the forms appeared perfectly distinct by degrees they became visibly less plain without decreasing in number as had often formerly been the case. The figures did not move off neither did they vanish which also had usually happened on other occasions. In this instance they dissolved immediately into an of some even whole pieces remained for a length of time which also by degrees were lost to the eye. At about 8 o'clock there did not remain a vestige of any of them, and I have never since experienced any apparition of the same kind. Twice or three since that time I have felt a propensity if I may be allowed to so express myself or a sensation as if I saw something which in a moment again was gone.

Mackenzie gives in addition various references to the subject, which seems to have been one on which there was more written at the beginning of the nineteenth century than at the beginning of the twentieth.

Francis Galton, in his book *Inquiries into Human Faculty*, relates the instance of a lady who was able to visualize "faces." He says:

A near relative of my own had them in a marked degree. She was eminently sane and of such good constitution that her faculties were hardly impaired until near her death at 80. She frequently described them to me. It gave her amusement during an idle hour to watch these faces for their expression was always pleasing though never strikingly beautiful. No two faces were ever alike and no face ever resembled that of any acquaintance. When she was not well the faces usually came easier to her sometimes almost suffocatingly close. She never mistook them for reality although they were very distinct.

Galton, in 1880 circulated a number of questions, with the object of eliciting the degree in which different persons possess the power of seeing images in their minds eye and of reviving past sensations. They are published at the end of the Eyerman edition of Galton's book and the fourteen in number as a result Galton proved how large a number of people are visualizers—that is to say who can, and do depend largely on visualization of places, persons, and things, and to whom to memorize a fact or event is to see it.

Those of whom he wrote were sane and healthy people, but were subject to visual presentations for which they could not account and which in a few cases reached the level of hallucinations. These visual presentations comprised:

- (1) number forms—that is, about 5 per cent of adults always associated a number with its own particular position in the mental field of vision,
- (2) assertions of colour with sound,
- (3) visualized pictures connected with certain words,
- (4) visualized pictures obtained by mental concentration,
- and (5) moving processions of men and faces when in the hypnagogic state.

Galton again writes:

that the mere acts of fasting or want of sleep and of solitary musing are severally conducive to visions. I have myself been told of cases in which persons accidentally long deprived of food became subject to them. One was of a pleasure party driven out to sea and not being able to reach the coast till nightfall landed at a place where they got shelter but nothing to eat. They were mentally at ease and conscious of safety but they were all troubled with visions half dreams and half hallucinations.

The cases of visions following protracted wakefulness are well known and I also have collected a few.

As regards the maddening effect of solitariness it may be sufficiently inferred from the recognized advantages of social amusement in the treatment of the insane. It follows that the spiritual discipline undergone for the purpose of self-control and self-motivation has also the incidental effect of producing visions. It is to be expected that these should often bear a close relation to the prevalent subjects of thought and although they may be really no more than the products of one portion of the brain which another portion or the same brain is engaged in contemplating, they often through terror receive a religious sanction. This is notably the case among half-civilized races.

The form these visions take may have some relation to previous experiences. A "hoarse" man sees a procession

of horses. A patient of mine, who has a peculiar dislike of spiders and such like animals, always sees a spider like animal. This is probably the result of the disgust he experienced when viewing spiders on some previous occasion, and has resulted in a marked sensitization of his visual memory centre, whereby he was able to picture more easily what he would fain forget. Compare Lady Macbeth's remark to Macbeth as he visualizes the ghost of Banquo, "The very painting of your fear" (Act iii, Sc 4).

Mr. Bernard Shaw writes in his preface to the play of *St. Joan*:

"The most sceptical scientific reader may accept as a flat fact carrying no implication of unsoundness of mind that Joan was what Francis Galton and other modern investigators of human faculty call a visualizer. She saw imaginary sights just as some other people see imaginary diagrams and landscapes with numbers dotted about them and are thereby able to perform feats of memory and arithmetic impossible to non-visualizers. Visualizers will understand this at once. Non-visualizers who have never read Galton will be puzzled and incredulous. And a very little inquiry among their acquaintances will reveal to them that the mind's eye is more or less a magic lantern and that the street is full of normally sane people who have hallucinations of all sorts which they believe to be part of the normal permanent equipment of all human beings."

Recently a medical man sent me the following letter:

You asked me to send you a few notes of my visualization. My personal experience is confined to a somewhat definite period subsequent to the choroidal haemorrhage which occurred on October 1st 1922, not immediately but a few months after. As far as I can recollect it was about the time when you were afraid that some fresh activity might be going on in the eye. I have never had my tendency to visualize before nor have I had it lately. The appearances took the form of men's heads and faces only. They were of life size standing close to and immediately in front of me usually one at a time but others would come forward and take his place. All the faces were similar—grotesque and horribly ugly, making hideous grimaces and facial contortions. They were all of the same colour of a dingy brown. Their appearances were of short duration. I had several but perhaps not many of them. They looked absolutely real and definite quite unlike a memory picture. I could not associate these productions with any special condition of stimulus nor do I think they ever occurred in bed (I am not one to be awake). They always occurred with the eyes closed and never intruded into the ordinary field of vision. Another visual sensation I experienced was quite different in character and occurred at about the same period. It consisted of a reticulated pattern superimposed on the ground and walls. The pattern was quite regular and usually small but sometimes it formed a network of larger meshes but the size was the same on each separate occasion. I saw this always in dull light. I have had two other kinds of spectra which perhaps are not relevant to the point of inquiry but I will mention them. The first I have had throughout the whole period of my eye trouble. It was frequent at the beginning and for some time after and I sometimes get it now. Its appearance is that of a ring of very bright light with a black interior and a few loop like lines of light but not a network. The figure would remain near the centre of the field of vision in constant vibration for many seconds then disappearing and reappearing. These figures have always been identical except of late the light has been much feebler and sometimes the bright lines of the interior are absent. The second kind of spectrum is simply that of round oval or broad banded patches of light passing rapidly across the field and disappearing. These I sometimes get now.

The interesting point to consider is whether these hallucinations depend on pathological optical conditions—that is, on defective retinal impressions—or on a central cause. Although in some of these patients retinal troubles and uterine sclerotic changes have been present, in others, and those perhaps the majority, there has been no organic retinal or ocular disability at all. It seems more likely that the cause is oversensitiveness of certain areas of the brain. My visualizers recount that the power to visualize was always existent, and was developed during childhood. It is not only "visualizers" who suffer from these visual phenomena, however, is my patient D. F. V. definitely records that he was not as a young man a visualizer.

We have evidence, then, that under normal conditions as well as under pathological ones, some people, possibly a large number, can visualize more or less distinctly—that is to say, they can present to their mind's eye a definite picture of people or things, this presentation being entirely subjective. We also have a condition exactly the reverse of this—an absence of power to visualize objects which have been seen again and again, or to reproduce to the mind's eye letters, words, or figures which have been gazed at for a long time and on many occasions, this condition may be congenital, or may be the direct consequence of disease. If the sensations derived from visual stimuli are not retained

by the visual memory centres at all, we reach the condition of letter, word, or mind blindness. In the higher forms of visualization we have the reverse of the so-called "word blind" condition in the one case the centres, or their connections with the rest of the brain, are undeveloped or under-sensitive, and in the other they are unusually developed or over-sensitive.

Though there are very different degrees of retentiveness of visual memory, still every normal human being endowed with vision possesses some capacity and miles could it use of it, in the recognition and interpretation of objects which come within his field of vision.

Past visual impressions are arranged in definite groups within the visual memory area, so that one or more of these groups may disappear without any interference with the others, and in this way are produced the conditions known as aphasia, agnosia, amnesia, etc. It is probable that the visual memory centre for objects, places, form, and colour are in different areas from those for visual memory of words, letters and figures but that they are contiguous. We have different capacities for registering numbers, words, colours, places, etc., which also vary in degree but we should suspect an individual sensitiveness in certain areas or domains of the brain in visualizers, and in the word blind a defect in similar areas. The centres for visual memory, we believe, in the angular, inferior parietal, and occipital lobe on the convex outer surface of the brain, beyond but close to the centres for word blindness, etc., which are in the left angular gyrus. There must be a sensation fibres between these centres and the visual centres situated on the inner surface of the occipital lobe, the hallucinations of "processions" are probably subcortical in origin.

With regard to the patients commented on here, the visual hallucinations have been present in sighted people, and during my work at St. Dunstons among totally blind men I never had any patient who related similar symptoms.

I think there is not much doubt that in the case of D. I. V. the hallucinations were seen on the right side—that is, in that part of the field of vision which retained sight—and that they disappeared on passing to the left, and were not visible in the blind area. I am told, however, that visual hallucinations have been recorded as occurring in the blind area of a hemianopic patient. People who are born blind do not see visual hallucinations, but may suffer from auditory or tactile ones, and the statement that visual hallucinations occur in the blind is true only of those who have subsequently become blind, and then the visions are probably very indefinite in appearance.

In conclusion, then, we have a series of conditions beginning with those whose capacity to visualize is so great that they can reproduce in their mind's eye a "vision" which appears to them to be almost substantial. Others less acute can "see" faces, figures, etc., in a definite position in space, and sometimes at will, and there are others who memorize by a visual capacity, which is only possible by mental concentration and for a varying but limited time, this group probably comprises the majority of ordinary folk. Others, again, do not memorize by vision at all, then memory is consequently often a weak part of their mental equipment. Lastly, we have at the other end of the scale the "word blind," who cannot visualize words, letters, etc., in which they have been gazing for some time, and who are unable to retain any impression, even the most transient. We have, therefore, the Giltane visualizer at one end of the scale and the totally "word" and "letter blind" at the other, and all these differences may be present in entirely sane people. On the pathological side, however, the series would run from the cases of delusional insanity to that instance described by Huchelwood where, as a result of cerebral haemorrhage in the occipital cortex, a man, aged 58, lost the power of reading because he could not remember for even a second what was the special significance of the letter or word seen—that is to say, he had lost his visual memory for letters or words.

In conclusion, then, these patients who suffer from this unhappy fate of constantly seeing unwanted forms and faces have possibly some functional derangement of those

area in the cerebral cortex or subcortex which lie in the inferior parietal and occipital lobes on their convex surface, and I submit that the derangement is due, not to any definite organic cause, but probably to a hypersensitization, owing to which aberrant stimuli are able to produce effects which are usually the result of definite visual stimuli.

I cannot say that one obtains much success in treating this unfortunate malady. If, as I suggest, it is due to an over-sensitiveness of the visual memory areas, tonics, bromide, and other treatments directed to improving the general health seem to be the only method open to us, but we must remember that peripheral stimulation is capable of arousing this phenomenon, as in the case of Dr. L., who had a definite central choroiditis, and these pathological ocular conditions may be amenable to treatment.

DISCUSSION

Mr. P. G. DOWNE (London) said that he had investigated a certain number of cases (taken at random) to find out whether they projected or visualized the alphabet in any particularly definite way. He was induced to do so as he himself had a very definite projection picture of the alphabet. He always visualized the letters of the alphabet in the form of a spiral running from above downwards—A in the top left-hand corner, and Z down and to the right. He found that in about one-third of the cases examined there was a very distinct visualization of the alphabet in some definite arrangement.

Dr. A. E. DAVIS (New York) said that if patients suffering from delirium tremens might be considered sane he would like to report some observations made a number of years ago in conjunction with Dr. C. I. DANA in the delirium tremens wards of Bellevue Hospital, New York. In the ophthalmoscopic examination of these patients it was observed that the retinal veins were enormously enlarged, tortuous, full of dark blood, and pulsating. Many of these patients saw snakes and it occurred to him that these visual hallucinations might have a physiological basis, the retinal veins being so large, full of dark blood, and pulsating, the images of these vessels were perhaps projected into the field of vision, thus giving rise to the illusion of seeing snakes. Of course, the patients were much confused mentally, and the visual illusions or delusions were more easily accounted for by their mental condition.

Dr. L. WEBSTER FOX (Philadelphia) felt greatly indebted to Mr. Osmond for describing a series of cases paralleling patients of which they had many in America where their cases were separated into two divisions—those which could be relieved by wearing amethyst or Crookes's lenses, the refraction being fully corrected, and secondly, those benefited by medicinal and electrical treatment. They found the iodides of great value with the addition of small quantities of bromides, and the application of the constant current 3 to 5 milliamperes daily, the negative pole to the eye. They attributed much of this affliction to their bright climate coupled with a highly neurotic constitution.

PHLYCTENULAR CONJUNCTIVITIS AND KERATITIS CAUSES AND PREVENTION

BY

N. BISHOP HARMAN, M.A., M.B.CANTAB.,
F.R.C.S. Eng.

Senior Ophthalmic Surgeon to the West London Hospital and the Belgrave Hospital for Children.

MACKENZIE, writing in 1830, at a time when the remembrance of the terrible epidemics of Egyptian ophthalmia was fresh in his mind—for he dealt with these epidemics at length in his textbook—says of phlyctenular conjunctivitis:

Neglected or mistreated, it becomes the frequent source of permanent impaired vision, or even of entire loss of sight. In a later passage he describes the disease as 'the first manifestation of a scrofulous constitution.' My aim

in this paper is to examine these two statements. Is the disease still a frequent source of serious damage to the eyes, and is it the first manifestation of struma, which means to us tuberculosis?

Phlyctenular Lesions as a Cause of Blindness

In my return of the causes of blindness in school children, in a total of 3,300 children who had passed through the schools for the blind and the myope classes in London, there were 699 whose disability was caused by inflammation of the superficies of the eyes. Of these 357 had suffered from ophthalmia neonatorum, 90 from purulent conjunctivitis of later years, and 242 from phlyctenular keratitis. Amongst school children the disease we are considering ranks next to ophthalmia neonatorum as a cause of educational blindness from superficial inflammation, it damages many more eyes than purulent conjunctivitis following the exanthemata and streptococcal infections. Of the 242 cases recorded 69 had such badly damaged eyes that they needed to be turned in schools for the blind, whilst 176 had vision so much reduced that they had to be taught in the myope classes. These figures take no account of the many other children whose sight, of one or both eyes, had been slightly damaged, but who were considered capable of being accommodated suitably in the elementary school under conditions of "easy treatment as regards eye work." The 69 who were in the blind schools account for 3.56 per cent of the total blindness amongst the school children, or, if we take the total of 242 in blind schools and myope classes, the percentage reaches 7.3 of all included in the two types of school.

These figures show that Mackenzie's statement of the damaging effects of the disease is still true, and that his warning against neglect and mistreatment still holds.

Etiology

1 *Social Factor*—The general conditions in which the disease is found are easily determined. A comparison of the records of private cases and of hospital patients will show how rare is the disease amongst the middle classes, and how common it is amongst the poorer classes. Again, a comparison of its incidence amongst different types of hospital patients is informative. In one classification of cases a separation was made between native and alien (Jewish) hospital patients: native patients outnumbered aliens by 3 to 1. But infections, conjunctivitis, blepharitis, and the like were much more common amongst aliens than natives—5 to 4, whereas phlyctenules were more common amongst natives than aliens—3 to 1. The differences between private and hospital patients, and between native and alien hospital patients, make it evident that some social condition is a determining factor in the liability to the disease. It cannot be racial, for race does not divide private and hospital patients; it cannot be a difference in cleanliness, for that does not divide the native and alien patients—indeed, so far as dirt infections are concerned the aliens are the greater sufferers. The social condition must be the lack of something that is common to private patients and the alien hospital patients. I think there can be no doubt it is the food factor. Our children are well fed, they do not suffer from phlyctenules, the alien Jewish children are equally well fed with a diet into which oil largely enters, and these children escape the ravages of phlyctenules.

2 *Age Incidence*—The second point bearing on the causation is the age of incidence. Figures derived from both a children's hospital and from an eye hospital agree in showing that there is a high peak of incidence at the fifth year of life. At the children's hospital no cases were seen amongst infants under 1 year of age, 22 were of 2 years, 35 of 3, 43 of 4, 55 of 5, and thereafter there was as steady a decline as there had been an uprise. At the age of 5 years the months of these poor children are in a pitiful state, and therewith are found repeated attacks of nasal catarrh, herpes of the lips, impetigo of the face—all plentiful sources of irritation to the fifth year.

3 *Seat of Election*—The plotting out of the site of the initial lesion of phlyctenular attacks shows that the lower and outer sector of the limbus is the most common site of onset, for 38 per cent occurred there. A further 28 per

cent appeared on the cornea just internal to this same sector, so that together 65 per cent. more in this one region. Lesions arising in other parts of the cornea and conjunctiva were few and about equally distributed except that none were found on the conjunctiva under the upper lid, and very few on the conjunctiva of the nasal sector. The nerve supply of the area of the most common site of the phlyctenules is derived from the loop formed by a twig from the lacrimal nerve and from the second division of the fifth, so that irritation within the month will well explain the concurrence of these eruptions of the richly innervated limbus, and the link of connexion with the lacrimal nerve will well account for the profuse lachrymation that accompanies these attacks.

4 Bacteriological Investigations.—Results have differed in different hands. My own investigations show that the majority of the fresh smears on phlyctenules are sterile and that during the height of the attack the conjunctiva is more free from the common pus-forming organisms of the mucosa than at any other time. The finding is quite otherwise in the later stages, when the phlyctenule has broken down into a surface ulcer, then a variety of organisms are found, mostly staphylococci. The conclusion from the observations is that the lesion is not directly due to a microbial invasion of the ocular tissue affected.

5 Seasonal Incidence.—Conjunctivitis in this country is undoubtedly more common during the second quarter of the year, when the earth is drying, the winds are high, and the sun is getting hot. An epidemic of trachoma during 1924 amongst the children at the dock area of London illustrates this well, during the first quarter of the year 17 cases were reported, during the second 121, in the third 57, and in the fourth 20. The outbreak was at its height at mid-summer, when all forms of conjunctivitis were rare. It is otherwise with phlyctenules. There is no early summer peak and but little difference throughout the year except for slightly heavier incidence in the winter quarter of January, February, and March, so that this disease does not connect with the disease of dirt infection such as are the various forms of conjunctivitis.

Histology.—The earliest investigators believed the lesion to be a minute blister, hence the name. MacKenzie writes of the "thin and colorless" fluid that escapes from them. Later workers, on cutting sections of the lesions, found them, or judged them to be, solid. To the skilled eye investigator, who pricks these lesions under appropriate conditions, there can be little doubt that they collapse like blisters, but when hardened and cut they seem to be solid. Even then, however, there are evidences of fluid contents, for links of fibrin are to be found which indicate that there was a fluid content which has been coagulated by the method of preparation. The conclusion is that the earliest writers were correct in their description of the lesion. It is a blister.

Six points of evidence have been cited: (1) Poor ill-fed children are alone affected. (2) The age incidence coincides with chronic conditions in other areas of the fifth nerve. (3) The sort of lesion confirms a causal relationship. (4) The freedom from microbial contents eliminates local infection. (5) There is no seasonal outbreak. (6) The histology is that of a hepatic blister. These six points of evidence converge on a general conclusion: that the disease is primarily constitutional and not local, that it is a manifestation of some general disability and not a specific infection of the tissues of the eye.

Struma

The general conclusion so far is on parallel lines with that of MacKenzie, when he writes that the disease is "the first manifestation of a scrofulous constitution." But much will depend upon what he meant by scrofula, and what we mean by this term now. We mean tuberculosis due to bovine infection. It is by no means certain that there was any such general meaning in the term when he used it, altogether apart from the absence of knowledge of a specific bacterial infection. In some of the past usages it appears to have no more meaning than that of a general physical enfeeblement, and in that sense his statement will cover our findings. In other old statements the word did connote

what we know is bovine tuberculosis, thus in early encyclopaedia gave the following definition: "External scrofula, attended by glandular swellings, external ulcerations and indolent abscesses. Called also King's evil and tubercle glandularis." In my record of cases of phlyctenular disease I find no confirmation of the idea that a majority or even many of these cases are associated with tubercle. In the majority of cases recovered fit to testify for so serious a primary origin. Of the cases seen at the children's hospital built very well, often one well, and all except a small minority were well before one month had passed. A minority of 3 per cent. included all those severe and chronic relapsing cases which tend to drag on for many months.

Of the 242 cases admitted to the blind and myope clinics no fewer than 60 showed active nose, ear or throat trouble, and only 2 tuberculous lesions. Last year I examined 321 children with a view to their transfer to the country ophthalmic school. Of these 240, or 74 per cent., were cases of conjunctivitis, mainly trachoma or severe blepharitis, and 81, or 35 per cent., phlyctenular disease. Of the latter only one showed what was reported to be a lesion of surgical tuberculosis, but even that was proved on inquiry to have been primarily an accidental injury. At the examination of the children it is my habit to note associated conditions: state of mouth, throat, etc. The children come from the same districts and might be expected to show a general equality of associated symptoms at the basic constitutional symptoms are the same. Of the 240 cases of conjunctivitis 12.5 per cent. had enlarged tonsils and 87.5 normal throats. Of the 81 cases of relapsing phlyctenular disease 30 per cent. had enlarged tonsils and 69.9 per cent. normal throats. So that there was in the children collected from the same areas and of the same social status in the one group of phlyctenular disease two and a half times as frequent throat affections as in those suffering from dirt inflammations. Again 60 of such cases of relapsing phlyctenular disease with chronic throat affections were referred in the past two years for throat treatment before decision as to transfer to the country. Of these 45 did not need transfer after operation but were returned to the elementary schools under various arrangements, and 12 were ultimately sent to Swanley, for they were no better after operation. The effects of treatment of associated conditions in the relief of relapsing keratitis is demonstrated by this experience.

Occasional incidents in the use of tuberculin injections have been held to be evidence that the lesions are definitely tuberculous. The injection of tuberculin has been followed by a crop of phlyctenules and some obstinate cases of relapsing keratitis have been improved by the injection. But this is not conclusive evidence of the tuberculous origin of the lesions. Other and non-bacterial products will cause outbreaks of phlyctenules even the application of atropine. Also a stopping of relapsing keratitis may be secured by injections other than tuberculin through an action known as protein shock. A sudden change of treatment as from atropine to eserine will sometimes bring a cure, and, speediest of all, the singular blocking of the vascular loops penetrating the cornea by the touch of the actual cauterizer.

That phlyctenular lesions are as common or possibly more common amongst children affected with tubercle is likely because there is in these a lowered vitality and a great susceptibility to any lesions that enfeebled children are liable to. But the evidence given tends to show that the primary general condition is not tuberculous but feebleness due to lack of proper food, and perhaps also lack of sun and air.

Prevention

The prevention of these lesions which damage so severely the eyes of some school children and render them less capable citizens in after-life is bound up with the general social betterment of the people. To this end there is no better agency than the school medical service. The school doctors are daily engaged in seeing out children of feeble habit those with infected mouths and throats and in securing treatment for both general and local conditions.

The provision of open-air schools for the debilitated is better treatment than exempting them from school, when they will get no such conservative attention. Dental and throat treatment are better than much medication. The transfer of those with affected eyes to country hospital schools, through such an arrangement as there is in London between the County Council and the Metropolitan Asylums Board, is better than many months of hospital treatment as an out-patient or even as an in-patient in a city hospital. And the results obtained through these measures, expensive as they appear to be at first glance, render them economical in the highest degree when the saving in effective citizenship is cast into the balance.

AN INSTRUMENT FOR RECORDING LIGHT MINIMUM AND LIGHT DIFFERENCE

BY

R WALLACE HENRY, M.D.,
Leicester

In the *Ophthalmic Review* of February, 1896, I published some notes on light perception as an aid in diagnosis and prognosis in diseases of the eye, and described a photometer which I had made which appeared to be free from the error which existed in most of the photometers at that time in use—namely, that the test involved, not merely light perception pure and simple, but also other form factors, such as reading letters, counting apertures, and the like.

That instrument was briefly as follows. There was a long box, open at one end, through which the person under examination looked, having one eye shaded, the whole head being covered by a hood, which excluded all external light. At the other end was an aperture opposite which were nine discs of "15 oz" standard opal glass, so arranged that they could be swung back one by one. Behind these ran a bar on which, distant one-third of a metre from the box, was fixed a standard candle in a spring holder, which kept the flame at a fixed level, behind which was a shield to prevent any flickering from draught.

The patient having been kept in the dark for five minutes, the eye not under examination being shaded, looked straight into the box, and, as the discs were swung back one by one, was told to say when a glimmer of light was detected. The number of discs through which the light was seen was entered the figure being his "light minimum."

The late Sir H. Swanzy, Mr. Snell, and Mr. Liles took a considerable amount of interest in my experiments, and asked if it would not be possible to have a test for light difference on the same instrument. Owing to various circumstances the question was put aside until just before the war when it was perforce again interrupted. I then tried to find a suitable test for light difference and used again the standard candle which I had originally used in my light minimum test. It was found necessary to have two candles, and I was greatly indebted to Messrs. Weiss for making an instrument which theoretically should have proved satisfactory, but which in practice failed to give a reliable test owing to the impossibility of ensuring that the light given by two candles even though "standard" ones, was identical. Messrs. Rayner, with whom I had also discussed the problem and its difficulties, took a great deal of interest, both in making and in carrying out suggestions, and the instrument which I am about to demonstrate is the result of their collaboration. Experiment with it shows, I believe, that it is an efficient test for "light minimum," "light difference," and also "light adaptation," the last being in some cases very different from "light minimum."

The instrument comprises an oblong wooden box containing the optical system, standing on another box containing the electrical resistance, on one panel of which are the controls for regulating the light of two electric standard lamps which form part of the optical system. On one side of the top box is a scale graduated in percentages of the light which falls on two opal plates about as he described. The light at its brightest is taken to be 100 per cent. In future instruments, for convenience of working this scale will be placed on the same side of the instrument as the electrical controls.

The top box is divided half-way across by a fixed partition, in which are two central square apertures, and at one end is an eye-piece, through which the square apertures are viewed. The other half is divided lengthwise by a fixed partition, on one side of which is an opal screen, fixed midway down the compartment, and on the other side a movable opal screen, which can be racked up and down the length of the compartment, and which is connected with a pointer running to a scale outside the box. At the opposite end of the box from the eye-piece is a standard 2-candle power lamp housed in a metal box, and so adjusted that half its light falls on one opal screen and half on the other, reflected light from one screen to the other being prevented by the partition. The illuminated screens can be seen through their respective apertures on looking into the eye-piece.

In the box containing the lamp is a slot into which a plate of "daylight" glass is inserted, and it is possible to insert plates of different colours so that the light minimum, light adaptation, and light difference of coloured light can also be observed. There is a shutter which is slipped over one of the apertures when light

FIG 1.—The apparatus

FIG 2.—a moving screen b fixed screen c aperture through which the two fields are examined d shutter to cut out field of fixed intensity for light minimum and light adaptation tests e pointer wheel for moving screen f standard lamp g plane glass screen reflecting light into the eye for light adaptation test h hanging lamp for light accommodation test

minimum and light adaptation are being tested. This shutter is controlled by a knob outside the box. Underneath the eye-piece is a small electric lamp, the light from which may be reflected into the eye at regular intervals, and so flooding it with light prevents, in certain circumstances, the illuminated aperture being seen. The lamp is switched off and on at regular intervals by a clockwork mechanism.

The instrument is designed to be run off any town current, and is supplied with resistances which may be varied to suit the current and which breaks it down to 6 volts. These are in the lower box. The control panel has on it a knob controlling a regulating main resistance, marked 100, 150, 200, and 250 volts. If it were known what resistance would be required the arrangement of the resistance would be simplified to some extent.

At the top left-hand corner is a long sliding resistance, for final resistance adjustments, while to the left is an ammeter, e, two switches, one controlling the standard lamp, the other the flashing lamp, and a short sliding resistance, d, beneath the ammeter which shuts the standard lamp, allowing it to be dimmed below its normal light. In the centre at the bottom, is a plug contact for the main, and there are two plug contacts one for each lamp. There is also a fuse in a convenient situation. The flashing

circuit has the same resistance as the other (with the exception of the shunt on the left-hand side of the box), and as the ammeter is in one circuit, the resistance controls are coupled together so that the adjustment of the one automatically adjusts the other. In the flashing circuit is a clock switch and lamp.

To adjust the instrument for use plug into the main current, place the pointer of the knob at the nearest voltage below that of the town circuit, for example if the town supply is 230 volts put the pointer at 200. Move the long resistance on the left to the maximum position, and switch on the standard lamp; the ammeter will now show a reading. The sliding resistance should now be moved until the ammeter shows a reading of 0.5 amperes. When dimming it is better to use the short shunt resistance and not the long one. When using the instrument I first test the light difference, then light minimum, and finally light adaptation.

I do not propose to say anything about the findings in diseased eyes but rather to indicate what one may expect to find in normal eyes. The intensity of the light used for the light difference test is 0.5 amperes, which gives approximately 2 candle power. The left eye being shaded and the movable opal square being placed in a position in which the patient can see that it is distinctly brighter than the other square, it is gradually moved nearer to it until it is thought to be equally bright. Then, moving it to a position in which it is distinctly duller than the fixed opal square, it is brought nearer until again it is thought to be identical in brightness. The two positions, as shown on the scale, are added together and then sum entered as the light difference of the eye. The same process is then gone through with the left eye.

Many persons with healthy eyes have a light difference of "3," while in a few cases I have found that they have a light difference of "1" or even three quarters. I believe that the average for a healthy eye is about "3," and I do not find that the light difference is affected, at my rate up to 55 or 60 years of age, by the advance in years. It is essential in all the tests that the patient should look directly forward, as the inner side of the retina is much more sensitive to light than the macula region.

In testing for light minimum push the square back so that only one square is visible. Move the square back to the position marked 100 on the scale. Commence with the ammeter registering 0.1 amperes and gradually increase the amperage registered by 0.05's until a glimmer of light is seen. When this is noted move the illuminated square back until no light is detected and enter as light minimum the amperage and the percentage of light seen. For example, 0.22—40 per cent, or 0.25—20 per cent, as the case may be. Healthy eyes at my rate up to 40 years of age, even usually begin to detect a glimmer of light with the ammeter reading 0.22 but as age advances the light minimum gets poorer. Frequently an amperage reading of 0.24 or 0.25 ampere is required when over 50 years of age.

The final step is to test for light adaptation. Wind the clock, switch on both lamps. A flash of light follows lasting two seconds, followed by three seconds' darkness. The patient is asked if he still sees the glimmer which was seen before, and is told he will see it best just before the flash returns.

It is often necessary to increase the amperage reading from 0.22 to 0.23 or even higher before the glimmer of light is seen. As soon as it is detected again move the illuminated square back from the 100 position until the point is found when the light vanishes. It is advisable to move it backwards and forwards several times, as the patients are usually more uncertain of the vanishing point than when testing for light minimum. The figure is entered, as before, as the light adaptation of the eye. It is interesting to note that patients who have a normal light minimum but a poor light adaptation will tell you that when they come out of the light into a dull room they have to wait a few minutes before they see clearly.

When I first used the instrument I quite anticipated that if the light minimum in each eye was the same, the light adaptation would also be the same in each eye. This is not the case. While often this is so yet in

some instances there was as much as 40 or 50 per cent difference in light adaptation between two eyes which had the same light minimum although in every way the eyes appeared normal. Why this should be so I have no idea and would be glad to have some explanation if this has been noted before.

DISCUSSION

Mr. A. S. PRINCE (Newcastle upon Tyne) said that without claiming scientific accuracy for Dr. Henry's instrument he had been amazed by the unfailing help afforded by his very simple method of testing the light sense by rotating discs which had so far never let him down. If the light minimum chiefly failed there was some defect in the receptive part of the visual apparatus—namely the bacillary layer of the retina, the visual purple, or the choroid. If the light difference (I D) chiefly failed there was some defect in the conducting part of the apparatus—namely the nerve fibres either the optic nerve, the nerve fibre layer of the retina or its trophic centre, the ganglionic layer of the retina. This could be easily remembered by ascribing I D with O D—the optic disc. I D failed in optic neuritis, retinobulbar neuritis, and what was now called toxic amblyopia. It would be found that if the eyes were covered with 03 or 04 neutral tinted glasses after a couple of minutes to get the eyes adapted to the diminished illumination the results of testing the light sense with his discs were exactly the same as with the uncovered eyes. This was of enormous practical importance in cases of cataract when no details of the fundus could be seen. Three years ago a patient came to him with cataract in both eyes, one mature, the other fairly advanced. In the "mature" eye he found I M far more reduced than the I D, he hence wrote to her doctor saying that he suspected a macular haemorrhage, and that in his opinion operation was inadvisable in that eye. Some six months afterwards she saw him again; her cataract had been removed quite successfully, so far as the operation was concerned, but with no visual success. Ophthalmoscopic examination showed the remains of a large macular haemorrhage.

A CASE OF PERFORATING WOUND OF THE EYE, WITH RETENTION OF A PILC OF GLASS

BY

R. COLLY, M.B. DOMS,

Honorary Ophthalmic Surgeon Royal United Hospital, Bath.

The patient, Dr. C., was driving a car on the evening of January 1st, 1925 when he ran into a man whose head shattered the windscreen. The man was severely cut—the facial artery being severed. Dr. C. received a linear wound of the skin of the forehead and a perforating wound of the right eye.

On examination twenty to thirty minutes later there was an irregular perforating wound of this eye about 5 to 6 mm. long through the cornea sclera at the outer side, slightly below the horizontal, with a prolapse of the iris. There was a haze of the anterior chamber due to a hyphaemia, which was not a large one. The patient had only perception of light.

The prolapsed iris was removed, the pillars of the coloboma replaced as well as possible, and atropine instilled, with pad and bandage. I thought I saw an opacity of the lens. The eye did very well and a good view of the fundus was obtained by January 3rd. There was a star-shaped opacity at the posterior pole of the lens, and a piece of glass could be seen lying behind the outer part of the lens. The star-shaped opacity disappeared in a few days. The eye has remained quiet and white ever since, in fact, at no time was there any ebulgent injection except for the first few days. The vision, from being only perception of light, steadily improved as the hyphaemia absorbed, until it became as it is at present.

The condition on April 17th was R V 6/5 (less 4) c plus 05 vis 160° 6/5 L V 6/5. There was an irregular cono-scleral scar about 5 to 6 mm. long at the outer side of the right eye just below the horizontal, with a pear-shaped pupil—the point towards the wound. Both pillars of the coloboma

were slightly adherent to the corner at the site of the wound. The pupil reacted well to light, and tension of the eye was normal, the lens was clear. The piece of glass could be seen lying behind the outer part of the lens. The glass, as measured roughly through the corner, appeared to be about 7 to 8 mm. in length and about 4 mm. in width, and roughly triangular in shape. It was immobile during movements of the eye and had some pigment spots on it. The fundus was normal.

The condition on June 5th was R V 6/5 without glass, I V 6/5. Apart from slight improvement of vision, the right eye was as on April 17th.

The condition on July 10th was R V with and without glass = 6/5 and J 1 L V 6/5 and J 1. The piece of glass appeared to be a little further away from the lens than it was at the last examination, otherwise the condition of the right eye was the same. The x-ray examination was negative.

My reasons for showing the case are

(1) The happy result, in that the vision is normal, 6/5 and J 1, the cosmetic effect is good, and the patient suffers no trouble or inconvenience.

(2) The fact that the piece of glass can be seen behind the lens quite easily.

(3) It adds one more case to a long list showing that various injuries to the eye due to glass are often followed by good results. The reasons suggested for this are: Glass appears to be fairly aseptic—probably owing to the smooth and polished surface, as mentioned in respect to spectacle glass by D. V. Cuth in the *British Journal of Ophthalmology*, 1919 vol 3, p 159, where he quotes Harb, who states that a well polished surgical instrument can be rendered germ free or nearly so by simple mechanical rubbing. An ordinary windscreen, however, does not suggest asepsis, but possibly the piece of glass came from the deep layers of the windscreen. Being sharp, often a great force is necessary for glass to penetrate, and thus the eye is not disorganized. Glass is chemically inert.

(4) The prognosis seems good, for the following reasons. Apart from the first few days the eye has never shown any irritation and remained quiet ever since accident. The glass appears to be quite immobile during the movements of the eye to be in practically the same position as it was originally, and not to be pressing on any important structure. Judging from the literature on the subject, I think one is justified in giving a fairly good prognosis in this case.

Numerous cases have been reported in which a piece of glass has remained in the eye for years. In the *Transactions of the Ophthalmological Society of the United Kingdom*, vol xvi, p 290, Mr J. H. Fisher reports two cases of removal of glass from the eyeball. In the discussion which followed, the late Mr Devereux Marshall referred to a case which had been under the late Sir J. Tweedy in which a large amount of glass was left in the eye and the vision was 6/6 and J 1 twelve to thirteen years later but by this time the lens appeared to be becoming opaque. Also on the same occasion the late Mr Huxtridge mentioned a case of a piece of glass projecting above the optic disc of five years' standing and the vision was 6/5.

In the *American Journal of Surgery* vol xxxi, 1922, p 228 the late Mr J. H. Claiborne reported a case of removal of a piece of glass from the interior of the eye—the interior chamber—after thirteen years. The glass was originally in the lens which became opaque after some years, and was absorbed.

In the *British Medical Journal* of 1888 vol i pp 895 and 1215 Mr T. H. Bickerton reported two cases of removal of pieces of glass from the eye—in the first from the interior chamber where the glass had been for ten years, and in the second also from the interior chamber the lens had been injured and absorbed. In this case the glass had been in the eye for seven years.

Thus from the few cases I have mentioned it seems that the eye can tolerate glass for long periods if the glass is not pressing on important structures though in the first case mentioned by Mr Bickerton the glass was lying in the interior chamber and apparently only caused irritation when active exercise was taken.

In conclusion I should like to thank our President, Mr Beaumont, who saw the patient with me at the time of the accident, Mr Cyril Walker, who saw the patient on two occasions and examined him on the slit lamp and Dr Macleay for the x-ray examination.

DISCUSSION

Dr H. H. Tyson (New York) said that some twenty-five years ago he saw a case in the late Dr Horn in Knapp's hospital in New York in which a rectangular piece of glass had remained encapsulated in the retina for over ten years. As the eye was quiet and vision good no interference was attempted.

Dr CHAMBERS JAMESON (Brooklyn, New York) said he would like to discuss Mr Colley's paper in which he obtained such an excellent result, not so much from the standpoint of a returned foreign body but that of a perforating wound of the cornea with prolapsus or incarceration of iris. In the last ten or fifteen years he had many times adopted a method of replacement, which he had outlined in the *Archives of Ophthalmology* some years ago. It was adapted to select cases of prolapsus, principally where the wound was small and encircled, and in which the period of incarceration had been of short duration. The examination of cases had ranged from seven to forty-eight hours after the injury. The method consisted in making a counter opening in the periphery of the cornea, passing a delicate bent blunt hook around the neck of the incarceration within the chamber and by gentle pressure without, and still more careful traction on the hook from within, the prolapsus was reduced and the iris replaced unharmed. There was no danger of injuring the lens as the hook was introduced in front of the iris. He sterilized the prolapsed iris before replacement with a solution of silver nitrate. The method had several advantages: (1) It brought into use two forces for replacement instead of one—namely, slight pressure and replacement from without and moderate traction from within the chamber. (2) It equalized the flow of aqueous diverting it in part from the wound to the counter opening, thus lessening the danger of prolapse after replacement, as well as enabling the surfaces of the wound to approximate and heal. (3) It permitted free sterilization as saline solution could be passed from wound to counter opening. (4) It prevented mutilation of the iris, the leaving of an unsightly coloboma of the iris (in case of excision), and also the exposing of the vessel system to infection. In many cases the eye was restored to its normal appearance, with no detection of any evidence of injury.

Mr THOMAS H. BICKERTON (Liverpool) said that in several cases of acute glaucoma the constant application of ice had after some hours, reduced the tension to normal, which had remained permanent. In other cases, recurrence had occurred, and again been reduced to normal by ice. In other cases—and the majority—operation had become necessary.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL

SPHEROIDAL CELLED CARCINOMA OF OVARY IN A CHILD OF EIGHT

IN Mr S. J. Cameron's paper on malignant disease of the ovaries and Fallopian tubes read in the Section of Obstetrics and Gynaecology of the Annual Meeting¹ the youngest case of carcinoma of the ovaries quoted was over 19 years of age. In view of this the following case may be of interest.

A girl aged 8 years was brought to the South Devon Hospital Plymouth in the spring of 1923. She had complained for four days of pain in the lower abdomen. It was constant and severe, increasing very much during defaecation. For two days the lower abdomen had been seen to be swollen. The bowels had been open once daily and there had been no vomiting. Micturition had been normal. The child had been getting thin during the last month otherwise nothing unusual had been noticed about her.

She was a well grown girl normally developed and fairly well covered. Her expression was anxious but she did not look ill.

Reviews.

MEDICAL SOCIOLOGY

A recent volume of the *Traité de Pathologie Médicale et de Thérapeutique Appliquée* edited by Professor L. SANCHEZ and Dr. R. BARRAS, is concerned with medicine in relation to social services (*Médecine sociale*) and is the work of twenty writers. An introductory chapter by Dr. Camou reviews the history and purpose of social medicine, the various institutions and services engaged in its work, and developing it and the need of co-ordinated effort by all employed in improving the social condition of the people. The volume is divided into two parts—preventive medicine and curative medicine. The first part is devoted to social hygiene and care of school children, child welfare, adolescence, care of the aged, hygiene and social services in connection with the working class, workmen's compensation and public health measures, organization and administration of hospitals, kindergartens, alcohol and narcotic drugs, prevention of mental disease and care of mental defectives are dealt with successively in the chapters of the first part. The second part consists of some seventy pages and is not separated into chapters. It details the systems of training and organizing social workers for hospital and domestic work and the methods of supervision of factories and factory girls by fully superintendents.

The immense importance of combating the decline of population in France gives special interest to the chapters on the social protection of the rising generation. In the chapter on maternity, Professor Concheville discusses the care of the mother from the time of conception to the time of weaning. He attributes the excess of deaths over births in several years since 1890 solely to voluntary control of conception. The chapter on child welfare contains an exhaustive inquiry, amongst other matters into the causes of infantile mortality in France and the influence of disease, season, sex, social condition of parents, environment, feeding and illegitimacy. In the chapter on school life reference is made to the importance of determining the pupil's aptitude or inclination for any special work or profession and of directing his studies accordingly, a point in education that is more often honoured in the breach than in the observance. The contributors to the chapter on moral education are a Roman Catholic, a Jewish, and a Protestant clergyman who describe the facilities for physical and moral culture of the young afforded by their respective religious institutions and social services, such as hostels for young people, young men's and young women's Christian associations, and boy scout and girl guide movements. The care of the aged is considered from the point of view of old age pensions and asylums, of which there are good descriptions and illustrations.

The chapters on the hygiene and social conditions of the working classes and on workmen's compensation and public health insurance are of special interest in view of the important place these subjects occupy in the politics of most civilized countries at the present time. They review industrial legislation in France, especially the system of medical arrangements in factories, provision of facilities for mothers and management of infants while at work, and the organization and management of creches. As regards workmen's compensation the French system of making the employer liable and leaving him to cover himself by insurance is compared with the German system of a contributory payment by wage-earner and employer to a State fund. The German system is still in force and is preferred in Alsace Lorraine and commerce and agriculture, and to insure all persons employed in industry, earning less than £400 a year. They would be insured not only against accidents, but also against sickness, maternity, and death. Although 10 per cent of the wages half by the employer and half by the employee, would be contributed

Traité de Pathologie Médicale et de Thérapeutique Appliquée Publié sous la direction de L. SANCHEZ et R. BARRAS. I. Médecine sociale. Paris: Maloine et Fils, 1925. (Demy 8vo pp. viii + 775. 10 figures. Fr. 45.)

The tongue was very full, the temperature was 96° and the pulse 96. A tumour was visible in the left groin and the pulse below the umbilicus. It was firm to the touch and highly tender. On rectal examination a mass was palpable in the pouch of Douglas. A tentative diagnosis of impeded growth was made. At operation a solid tumour was found growing from the left ovary but extending beyond its envelope. The tumour was made encased except the right extremity which was tumorous and becoming adherent to coil of small intestine. The tumour was both ovarian and tubal in origin. No other focus of growth was seen. On microscopic examination the tumour proved to be a spheroidal cell carcinoma.

Twelve days after the operation enlarged glands appeared in the right groin and two days later in the left groin. The child then went home with a bag of pus. A month later she was readmitted with a tumour similar to the original one and nodules, one of which was tumorous, through the wound in the abdominal wall. She was caesarean and died ten days later. Terms could not be obtained for a post mortem examination.

I am indebted to Mr. H. G. Pinker, who has kindly allowed me to publish this case.

OLIVIA POTTIP, M.B., B.S.
Late Hon. Physician, South Devon
Hospital, Exmouth.

THE RECOGNITION OF LATENT JAUNDICE DURING TRIAL WITH ARSENICOBILIN

A paper on this subject by Surgeon Lieutenant-Commander W. I. GERRARD, Royal Naval Hospital Haslar, was published in the *British Medical Journal* last year (vol. ii, p. 224) and a little later (p. 542) Dr. A. M. STURRIT wrote to suggest that the cause of the frequency of the occurrence at Haslar was the intensity of the course. We have since received the following note:

During the past fifteen months at the Royal Naval Hospital Hong Kong 346 cases have been treated with arsenicobillin, three only have developed jaundice—an incidence of 0.86 per cent. Two were undoubtedly toxic in origin, the third doubtful. The cases are divided into three groups:

Injection No 1	A	B	C
No 2	0.45 gram	0.45 gram	0.45 gram
No 3	0.6	0.6	0.6
No 4	0.9	0.6	0.6
No 5	0.9	0.9	0.6
No 6	0.9	0.9	0.9
	0.9	0.9	0.9

Group A consisted of 123 cases, but as 14.6 per cent of reactions were occurring, the dose was reduced to that under Group B. In this group we still got 15.4 per cent reactions at the time and the dosage was further reduced to that under Group C. In 186 cases in this Group C the reactions at the time were reduced to 6.4 per cent.

In batches A and B no cases of jaundice occurred, but in the last batch, C—that is the batch given the smallest dose—all three recorded cases of jaundice occurred.

In every case the interval between the injections was the same (namely, three days) and the strength of the solutions used relatively the same—that is 0.45 gram arsenicobillin in 0.45 c.c. distilled water, 0.6 gram arsenicobillin in 0.6 c.c. distilled water, and 0.9 gram arsenicobillin in 0.9 c.c. distilled water. In every case the solution was filtered before injection through several thicknesses of gauze.

From the above experience it would appear that the intensity of the course has no bearing on the subsequent incidence of jaundice, in fact the smaller the total amount given the greater the incidence of jaundice. Possibly the reason for this Dr. Sturrit has recorded no cases of jaundice in following up the after-history in civilian practice.

H. W. FITZROY WILLIAMS, M.B., D.P.H.,
Surgeon Lieutenant-Commander R.N.

Hong Kong

to the compensation fund, the writer of this chapter considers that the State will have to contribute in addition some £20 000 000 annually (at par value of the franc) to meet the liabilities, and employ some 15,000 officials drawing £2,500,000 in salaries to administer the Act. This chapter contains much food for thought in connexion with the medical administration of workmen's insurance and the responsibilities it involves.

The chapter on hospitals contains some interesting tables, one of which compares the proportion of hospital beds to population in the principal cities of Europe. Rome has apparently the highest proportion, 9 per 1,000 inhabitants. Lyons with 8.7, Copenhagen with 8.1, and Brussels with 7.2 beds per 1,000 come next, while London with 4.2, Glasgow with 3.3, Liverpool with 3.2, and Manchester with only 2 beds per 1,000 inhabitants, the worst provided of all, compare unfavourably with the other cities. So far as the British hospitals are concerned these figures are, however, unreliable. They do not include for example, the accommodation in Poor Law infirmaries in the case of Manchester, where the number of Poor Law beds is nearly double that in the voluntary hospitals, and unless Poor Law beds are taken into consideration the hospital accommodation in Great Britain is not comparable with that of Continental countries.

The chapter on medical sociology in relation to alcohol and narcotic drugs is written by Dr Legrain, a strong advocate of prohibition. He has no faith in coercive measures, such as fines and imprisonment for drunkenness, and urges complete suppression of the manufacture of alcoholic drinks. In France, where viticulture is a national asset prohibition would appear to have no foothold, but Dr Legrain argues that neither the wine growers of the south nor the distillers of the north need suffer financially, for the grapes can be utilized profitably for the production of non-alcoholic foodstuffs, as is now being done in many parts of Switzerland, and the beetroot for increasing the production of sugar. His most impressive argument from a national point of view is that the production of wines, spirits, and beers uses up huge quantities of fruits, root crops, and cereals which would otherwise add to the food supplies of the country. The means of educating all classes to accept prohibition occupies a considerable portion of Dr Legrain's chapter. His remarks on the social evils of narcotic drugs and the means of suppressing them are comparatively brief. Eugenics and mental consulting clinics form a considerable section of an up to date chapter on the prevention of mental disease.

The volume contains a vast amount of useful information regarding the social institutions and social activities, both official and private in France and to some extent in other countries. It merits close study, not only by members of the medical profession, but also, and more especially, by statesmen, politicians, public officials, and all who are interested in improving the health and social conditions of the people. Lawyers, clergymen, public officials, and social workers, as well as members of the medical profession, have contributed to its pages.

THE ROOT CANALS OF THE TEETH

The shapes of the root canals have an obvious and important bearing on the vexed questions of the preservation of pulpless teeth and of the dangers of crowns. So long as a root canal was believed to be a single tube, more or less straight it was reasonable to assume that it, at least could be sterilized. But for some years evidence has been accumulating tending to show that simplicity is the exception rather than the rule. In a volume on *The Anatomy of the Root Canals of the Teeth* WALTER HERS and ERNST ZÜRCHER, both working at Zurich, publish the results of their extensive and laborious researches on this point. They have elaborated a method of using dental rubber which enables them eventually to dissolve

away the tooth and leave a accurate replica of the root canal and its ramifications. Their results show that simplicity is far from being the general rule. Simplicity is most likely to be found in early life before the closing of the apical foramen, and in late life when the whole pulp is calcified.

We must confess to being puzzled by what are called "marrow canals." These may connect the root canal with the periodontal membrane, and yet are described as absent in the earlier years of life. Are they, then, a result of absorption?

This small volume embodies a most valuable piece of work both for the dentist and the medical practitioner.

ANNALS OF MEDICAL HISTORY

The second quarterly instalment of the seventh volume of the *Annals of Medical History* contains ten original essays besides editorial articles and reviews, among the latter are two by the editor *A Surgical Pilgrim's Progress (1845-1925)*. *The Reminiscences of L. S. Pilcher* and the third edition of the late Sir Richard J. Godlee's *Life of Lord Lister*, while Dr F. M. Garrison speaks of Dr F. R. PICKARD's book on Guy Patin as written by "our best scholar in French and American medicine." The frontispiece represents the late Dr Robert Fletcher of the Surgeon-General's Library and the *Index Medicus* taken from a crayon drawing by the French artist P. Renouard. Dr Fletcher is supposed to be solemnly presiding at an anthropological meeting, and at his back are two diabolical faces by no means suggesting a serious assembly. The first article is on Chinese drug stores, which Dr K. K. Chen of Peking has illustrated by twelve figures including two prescriptions. Mr G. E. Bouquet describes the life and physiological researches of the Rev Stephen Hales especially his observations on arterial blood pressure which carried the study of the circulation beyond Harvey's work and introduced the method of quantitative investigation. Dr Jonathan Wright supplies a thoughtful essay on Plato's *Timaeus*, and Dr Louis J. Bragman gives the rules of physical hygiene formulated by Maimonides, the Jewish physician and philosopher of the twelfth century. Arminius Hansen (1841-1912), who was chief physician for leprosy in Norway from 1875, was, so his countryman Dr I. Kolbo tells us, a keen champion of Darwin's theory of evolution from the start, and was much influenced by D. C. Danielssen, the founder of scientific leprology. As showing the effect of Hansen's efforts, attention should be directed to the fact that there were 2,209 lepers in Norway in 1875, and only 140 in 1923. Dr J. Moores Ball gives an account of an "illegitimate son of Aesculapius," Samuel Thompson, who patented a "system" of medicine as set forth in his *New Guide to Health or Botanic Family Physician* (1835), to which was affixed a narrative of his life and "medical discoveries," which, Dr Ball remarks, amounted probably to nothing not previously known. Dr David Reisman, whose numerous contributions to the *Annals* are always interesting, writes on Thomas Sydenham, clinician and touches on the gulf that separates him from his great contemporary William Harvey. Perhaps the most attractive article in this number of the *Annals* is a selection from *Rambles in Europe in 1839* by William Gibson, professor of surgery in the University of Pennsylvania, published in 1841, this book is now so rare that Dr Pael and I have done well to present to us its pleasant personal sketches of the great men of that time, such as Sir Astley Cooper, Sir Benjamin Brodie, Samuel and Bransby Cooper, Liston, James Wardrop in London, and of Velpeau, Lisfranc, Ricord, Guerin, and Civiale in Paris. Elsewhere in this issue will be found an extract sent to us by Dr Rawson describing the annual meeting of the Provincial Medical and Surgical Association (which afterwards became the British Medical Association) in Liverpool in 1839. The reader will find in Dr Alexander Randall's notes on emphysemas in the collection of calculi in the Royal College of Surgeons of England some of the *spolia opima* of the surgeons described by Gibbon.

The Anatomy of the Root Canals of the Teeth of the Permanent Dentition. By Walter H. M.D. D.D.S. *The Anatomy of the Root Canals of the Teeth of the Deciduous Dentition and of the First Permanent Molars*. By Dr. Med. Dent. Ernst Zürcher. London: John Bale Sons and Daniels Ltd. 1925. (Roy. 8vo pp. 119, 1. 80 figures, 63 plates, 16 net.)

Annals of Medical History. June 1925, vol. vii, No. 2. Edited by Francis R. Pickard, M.D. New York: L. L. R. Hoeber, Inc. London: Baillière Tindall and Cox. (8½ x 11½, pp. 103, 202, illustrated. Subscription in Great Britain £2.2. for four numbers.)

THE MINISTRY OF HEALTH
Messrs PUTNAM have issued the second volume of their Whitehall series of handbooks. The subject of the first volume is the Home Office by a retired civil servant and the second devoted to the Ministry of Health, is by another retired civil servant, Sir Arthur Newsham, who was for seven years principal medical officer of the Local Government Board. In twenty chapters the author gives a succinct account of the development and operations of the central and local health authorities of England and Wales, a task for which he is well qualified by his own forty years' experience as a medical officer of health and as Principal Medical Officer to the Local Government Board. Apart from expressions of personal opinion on which there is always plenty of room for differences of view the book is a comprehensive and unimpeachable compilation of facts, and will be very useful to those for whom the Whitehall series is intended—members of Parliament, civil servants, municipal workers, journalists, students of administrative methods, young men and women thinking of the civil service as a career, and the general reader who is interested in the government of his country.

NOTES ON BOOKS

DR PAUL HAUDURY's recent monograph on *Le Bactériophage d'Hérèlle* is the first comprehensive study of this subject since the appearance of d'Hérèlle's work in 1921. Dr Haudury is specially qualified for this undertaking as he was one of the first to call to the importance of d'Hérèlle's phenomenon and has devoted particular attention to it in eight chapters, devoted respectively to the history of the bacteriophage, the phenomenon itself, the properties of the bacteriophage, and immunity with therapeutic applications, the technique of its isolation and the importance of d'Hérèlle's discovery. As Professor Bezançon says in the preface d'Hérèlle's discovery not only reveals a new invisible virus but also completely modifies the classical doctrine of immunity, and opens up new paths in prophylaxis and treatment. Dr Haudury's book is an admirably clear exposition of the subject which will be of interest alike to the bacteriologist and the clinician.

The work on the principal social narcotics by Dr LEGRAIN, the well known Parisian alienist, is based on his experience during the last thirty five years in his campaign against opium, alcohol, and tobacco. The first four chapters are devoted to the history and prevalence of the consumption of opium, special stress being laid on the part played by the European powers in pressing, as is alleged, the sale of opium in China. Then follows a short chapter on tobacco the use of which, according to the author, admits of no excuse whatsoever as it does not possess any therapeutic properties like opium, nor any alimentary properties like alcohol, but is merely a costly and dangerous narcotic. The remaining seven chapters deal with alcohol from the historical, sociological, and political standpoints. The second part consists of seven chapters in which the psychological aspects of endemic intoxication are considered. In the third part the remedies for these evils are discussed. Dr Legrain, who is an uncompromising advocate of total abstinence and prohibition, warmly upholds the preparation of non-alcoholic drinks from grapes, an industry which he says was first started in Switzerland in 1880. There are two appendices dealing respectively with the Opium Conference at Geneva in 1925 and the duties imposed on non-alcoholic drinks in various countries.

The recently published work on prostitution by the late Dr IWAN BLOCH and Dr GEORG LOEWENSTEIN represents the first half of the second volume on this subject. The first volume dealing with the history of prostitution from the earliest times until the end of the fifteenth century was

pp vi + 212 Fr 10)
* Les Grands Vénéreux Sociaux Par le Dr Legrain Paris A Maloine
et Fils 1925 (Cr 8vo pp 459 Fr 20)
* Die Prostitution Zweiter Band By Dr med Iwan
Bloch and Dr med Georg Loewenstein Erste bis vierte Auflage Berlin
Louis Mareu 1925 (Med 8vo pp viii + 728 M 12)

published in 1912. It is entirely written by Dr Bloch, who died ten years later, and the continuation of the work was entrusted to Dr Loewenstein of Berlin. The present instalment, which consists of ten chapters dealing with the history of prostitution from the appearance of syphilis at the time of the Renaissance until the end of the eighteenth century, is a mine of information for the medical historian and the venereologist. The second half of this volume is promised for the end of 1925.

Yourself and Your Body written by Dr W. T. GIFFELL of Labrador, is a children's textbook of anatomy and physiology. The story is told with all the tricks of the fairy tale, and illustrated with ingenious diagrams drawn by Dr Giffell himself. It is astonishing to find what complicated things Dr Giffell can explain in simple language and illustrations by pictures. Thus the chemistry of respiration, the digestion of food, and the functions of the central nervous system are made as engrossing as the tale of Little Red Riding Hood or Jack and the Beanstalk. Like many other books written for children, this too might be read with profit by many parents.

The eighth edition of *Income Tax and Super Tax Tabular* has been prepared with a view to providing information about income tax and super tax in a form which shall aid in the unravelling of tax liabilities and claims. Tables are provided showing the various allowances, and the money values of various totals of allowances, illustrations of the rules in operation, the actual return of dividend, with the tax at 5s, 4s 6d, and 4s respectively rates of super tax from its institution and the total super tax on various incomes. The particulars given cover this year's Budget. An abstract of the legal position is given in popular language, supplemented by a statement of nearly forty heads of repay, ment claims classified as relating to domestic concerns, land and buildings, and business. The publication should be found of considerable value, though it makes no claim to be a manual of income tax.

I lent Colonel SHAW, I.M.S., who has had experience as superintendent of three mental hospitals in India—Bangalore, Lahore, and Poona—successively, has written a *Clinical Handbook of Mental Diseases* in which an introduction on the nervous system and psychology, the different types of insanity are described. Three useful appendices deal with the transfer of Indian lunatics to England with military insane, and with the construction of mental hospitals in India. The work will be found useful by students and practitioners in that country. The type is clear, and we have noticed only two misprints.

MEDICAL AND SURGICAL APPLIANCES

Operating Boots
Mr Eric Pearce Gwyn MCh FRCs (London) writes: The operating boots here illustrated are the outcome of an attempt to obtain a legging which could be worn if desired over outdoor shoes and repeated sterilization by dry or moist heat be easily kept in place and wrap up into small compact form. The sole of the boot is made of a kind of rubber which is unaltered by boiling or steam and the upper is of white coutil which is washed well and is attached to the sole by hand sewing without the use of rubber solution. The single long flap in front allows the boot to be attached to a front brace button and the ankle flaps tied over the instep keep the foot portion in place. I have had one pair in constant use at hospital for the last nine months and they show as yet no signs of wear. I am indebted to Messrs Allen and Hanbury Wigmore Street W1 from whom the boots can now be obtained for the trouble they have taken in finding the right materials to meet the objects I had in view.

Res N 712509

THE BRITISH ASSOCIATION

THE ninety-fifth annual meeting of the British Association for the Advancement of Science began in Southampton on Wednesday, August 26th, when Major General Sir David Bence, A.M.S., F.R.S., was succeeded as President by Professor Horace Lamb, F.R.S., who held the chair of mathematics first in the University of Adelaide (1875-1885) and then in the University of Manchester (1885-1920). Among the thirteen sections are those of physiology, anthropology, psychology, and zoology.

The President's Address

The address delivered by the President on Wednesday evening fell into two parts, the first consisting of some reflections on the nature and purpose of science in general, and the second dealing with geophysics, a subject on which he is in acknowledged authority. In his opening remarks he said that the answer to the question, "What was the general aim of science?" was usually the almost consecrated formula, "To subdue the forces of nature to the service of man," as it was impossible to say what abstract research might not provide a clue to something useful; the more speculative branches of science were not only to be tolerated but to be encouraged within limits as ancillary to the supreme end. The President professed himself dissatisfied with this answer, though he recognized that practical utility had been a conscious but not the sole aim in much scientific work and sometimes perhaps its main justification, and continued as follows:

The primary aim of science is to explore the facts of nature to ascertain their mutual relations and to arrange them as far as possible into a consistent and intelligible scheme. It is this endeavour which is the true inspiration of scientific work, as success in it is the appropriate reward. The material effects come later, if at all and often by a very indirect path. We may I think claim for this constructive task something of an æsthetic character. The provinces of art and science are often held to be then and even antagonistic but in the higher processes of scientific thought it is often possible to trace an affinity. The mathematician at all events is at no loss for illustrations of this artistic faculty. A well ordered piece of algebraical analysis has sometimes been compared to a musical composition. This may seem fantastic to those whose only impression is that of a mass of curious symbols but these bear no more resemblance to the ideas which lie behind them than the equally weird notation of a symphony bears to the sounds which it connotes or the emotions which these evoke. And it is no misplaced analogy which has led enthusiasts to speak of the poetical charm of Lagrange's work or the massive architecture of Gauss's memoirs or the classic perfection of Maxwell's expositions. The devotees of other sciences will be at no loss for similar illustrations. Is it not the case for instance that the widespread interest excited by the latest achievements of physical science is due not to the hope of future profit though this will doubtless come but to the intrinsic beauty as well as the novelty of the visions which they unfold?

To draw a sharp antithesis between pure and applied science would, Professor Lamb said, be mischievous. The most severely utilitarian result had often been reached through a long and patient process of study and experiment conducted on strictly scientific methods. The duty pure science owed to industry must also be recognized through the impulse derived from the suggestion of new problems and the extended scale on which experiments became possible. The National Physical Laboratory initiated mainly in the higher interests of industry, had, through the pressure of the matters submitted to it, grown into a great institute of theoretical as well as applied science, informed throughout by the true spirit of research. Nevertheless, the most momentous consequences of the increased scientific activities of our time had been on the intellectual side. There was reason to rejoice that the conflict at one time keen and bitter, between authority and science over matters entirely within the province of the latter had become obsolete. One side had become more tolerant, the other less aggressive and there was a disposition on both sides to respect each other's territories. The quarrels were political rather than ecclesiastical. The habit of sober and accurate analysis which scientific pursuits tended to pro-

mote was not always favourable to social and economic theories which rested mainly on an emotional if very natural basis. A certain dumb hostility was to be traced which, without venturing on open attack, looked coldly on scientific work so far as it was directed to purposes of obvious and immediate practical utility.

Science was also exposed to another and more open kind of criticism in quarters where it might fairly look for countenance and sympathy. Its burden was disappointment and disillusion, and there were some who spoke of the "bribe rupter of science." This seemed to mean that science at one time or other had held out promises it had been impotent to fulfil, and had inspired vague hopes that had proved delusive. It might be admitted that extravagant and impossible claims had sometimes been made on behalf of science, but not by the real leaders, who had always been modest in their claims and guarded in their forecasts. In the enthusiasm which attended the first sensational developments of modern industry hopes were conceived of a new era, where prosperity would ever increase, poverty would be at least mitigated and refined, and national antipathies would be reconciled. When these dreams did not swiftly come true there was a reaction, the idols were cast down, and science in general had rather unreasonably come in for its share of depreciation. Science, however ought not to be held responsible for the failure of hopes which it never authorized. Its province, though vast, had its limits. It could have no pretension to improve human nature, it might alter the environment, multiply the resources, widen the intellectual prospect, but it could never fairly be asked to bear the responsibility for the use made of those gifts, that must be determined by other and higher considerations. "Medical science, for instance, can give us longer and healthier lives, it is not responsible for the use we make of those lives. It may give increased vitality to the wielder as well as the just, but we would not on that account close our hospitals or condemn our doctors." In spite of criticisms men of science might claim without arrogance but with confidence that their efforts had a place, not a mean one in human activities, and that they tended, often in unimagined ways, to increase the intellectual and the material, and even the æsthetic possessions of the world. "In that assurance we may rejoice that science has never been so widely and so enthusiastically cultivated as at the present time, with so complete sincerity or (we may claim) with more brilliant success, or even with less international jealousy."

Professor Lamb then turned to the discussion of certain problems in geophysics, dealing in particular with the figure of the earth and the variation of gravity, and expressed regret that the observational side of geophysics had been so little cultivated in this country. In India with its wide opportunities, geodetic and gravitation work had long been carried on with high efficiency but in the home country, although it had an admirable topographical survey, nothing had been done towards a gravimetric survey since the time of Kater, more than a century ago. Proposals for the establishment of a formal geodetic institute had been made before the war, but had to be abandoned owing to the exigencies of the time. It was therefore some satisfaction to record that a modest beginning had been made at Cambridge by the institution of a readership in geodesy. Turning then to the age of the earth, Professor Lamb observed that radioactive speculation founded on a comparison of the amounts of uranium and of the end products associated with it, had led to estimates of the time that had elapsed since the final consolidation of the earth's crust. The conclusions drawn would be willingly accepted by geologists and biologists as giving ample scope for the drama of evolution. Geophysics afforded instances of a way in which speculations which appeared remote from common interests might ultimately have an important influence on the progress of science. The history of science was full of examples where one branch of science had profited by another in unexpected ways. To promote this interaction between different branches of science was one of the most important functions of the British Association and differentiated it from the various sectional congresses held from time to time.

PREVENTION OF TUBERCULOSIS IN CHILDREN

PROFESSOR CALMETTE came to the conclusion after many years of laboratory research that acquired immunity to tuberculosis could only be reached by vaccinating with a living virus deprived of its capacity for producing the disease tuberculosis by some device of the laboratory such as that used by Pasteur in the preparation of his anthrax vaccine. Since the publication of his masterly treatise on tuberculosis Professor Calmette has been directing his research towards the discovery of such a vaccine. This living yet non-tuberculous virus ought to have the quality of being non-poisonous to susceptible animals and yet have the capacity of protecting animals not hitherto exposed to the tubercle infection. The communication he and certain colleagues made to the *Académie de Médecine* on June 16th encourages a hope that the objective of many years' study is within sight even if it has not already been reached. The communication was founded on the experience gained over a period of three years with a new vaccine designed to prevent the development of tuberculosis in infants born of tuberculous parents.

Both in its manner of preparation and method of administration this vaccine differs from previous preparations. The original source of the vaccine he now advises was an extremely virulent strain of the bovine type of tubercle bacillus which after more than 230 successive cultures on an alkaline medium over a period of thirteen years has been deprived completely and hereditarily of its capacity of initiating tuberculosis yet the microbe remains toxic for tuberculous animals, scatters tuberculum, and provokes the formation of antibodies in the same way as a virulent tubercle bacillus. The vaccine is known in France as BCG. It can be given without risk by mouth, intravenously or subcutaneously.

The results so far obtained with this vaccine have been most promising. In the first six months of 1922 178 infants born of tuberculous parents were vaccinated and in the three years which have since elapsed not a single one of these has died of tuberculosis, though 15 have died from other causes. Some of these vaccinated children have remained in the same homes as their phthisical parents, but show no signs of the disease. Apart from tuberculosis, the general mortality of the 178 children has been 8.4 per cent, a figure considerably lower than the infant mortality of other children in France. A preliminary communication about this work was published last year and in the intervening twelve months numerous demands have been made for the vaccine but the general supply has been reserved for the protection of infants born of tuberculous parents or exposed to infection in their homes. The vaccine has been given before food on the fourth, sixth, and eighth, or the first, seventh, and ninth days after birth. During the last twelve months 2,070 newborn children have received this vaccine in Paris and other parts of France.

¹ Reviewed in the *British Medical Journal* December 11th 1920 (p. 894).

and Belgium. Up to June 1st 1925, Professor Calmette had been able to trace 423 of these infants vaccinated at least six months previously, and none of them had died of a tuberculous infection, 30 deaths had actually occurred among these 423 children, a mortality of 7 per cent, and the only cause of death which might possibly have been of tuberculous nature was meningitis reported in two cases. These facts are noteworthy in view of the heavy toll which tuberculosis ordinarily exacts from the offspring of tuberculous parents.

The value of this new method of treatment is being tested by clinical and experimental methods. Under the heading 'Clinical' Professor Calmette describes research which has been inaugurated to discover the usual mortality rate of tuberculous mothers and the tuberculous mortality rate of infants born of tuberculous mothers. Though still in a preliminary stage this investigation has already revealed some striking facts. Thus it appears that every infant of a tuberculous mother not removed to a non-infectious environment has at least one chance in four of succumbing to tuberculosis in the course of the first year of its existence. In comparison with this the tuberculosis mortality of children vaccinated in 1922 was not less than 0.5 per cent for infants vaccinated between July 1st and November 30th 1924 and not also for those children 137 in number who have lived more or less constantly exposed to family contagion.

Professor Calmette has not reported in full all the experimental work which has been carried out on monkeys and calves. He promises that this shall be published shortly. Inference is, however, made on certain experiments on monkeys which may be summarized in one sentence—none of the vaccinated monkeys experimented with since 1923 have died of tuberculosis while all the other experimentally infected monkeys and all controls have contracted tuberculosis and succumbed in periods ranging from two to five months. Similar support has been obtained from experiments on calves. This work is still in progress and we are glad to note the statement that the BCG vaccine is being tested by veterinary surgeons in England. In many parts of France other than Paris and also in the French colonies the vaccine is being tried on an extensive scale. Professor Calmette makes no extravagant claims about this new plan for the protection of children. He modestly states that the only conclusion which can be drawn is that the vaccine may safely be used for the prevention of human and animal tuberculosis. It has proved completely harmless to all the children vaccinated over a period of three years and its efficacy for the protection of newborn children has been shown by clinical experience and substantiated by experimental tests.

VITAL STATISTICS OF ENGLAND AND WALES

The Health Organization of the League of Nations has issued in its series of statistical handbooks one dealing with England and Wales. It should prove extremely useful not only to the foreign readers for whom it is intended but even to some Englishmen who—unless they are preparing for a general knowledge paper set by the Civil Service Commissioners—may not be quite sure of the distinctions between the four senses in which the word 'county' is used in

¹ League of Nations Health Organization. Statistical Handbooks. Series No. 3. *Official Vital Statistics of England and Wales*. Geneva 1925. London Agents: Constable and Co. (1 p. 115 1 price 6d net.)

official statistical publications. Indeed, to use intelligently the vital statistics of this country—statistics which now cover, so far as population figures are concerned, 120 years, and, so far as rates of mortality are concerned, nearly 90 years of national life—the reader must have knowledge of an internal organization which has developed gradually and without breach of continuity through many centuries, and is difficult to understand because there persist vestiges of once very real but now quasi-obsolete jurisdictions. On this account the handbook, which strictly follows the original plan of providing an index of the contents of all the official documents, gives much prominence to explanations of the meaning of terms and to descriptions of the functions of different departments, and appends a short but well selected bibliography of the more important works containing fuller details.

The development of English vital statistics is briefly described. In this matter, as in larger affairs, one feels that we have, as a nation, had extraordinarily good luck. No doubt the generalizations of national character which novelists and epigrammatists affect are superficial, but there is surely some truth in the common saying that the Frenchman is a greater lover of logic and the German a greater lover of tidiness than Englishmen, while both French and German are far more docile in the presence of the bureaucrat than we. First-rate vital statistics appeal to the logician, to the lover of neatness, and to the permanent official, long odds might have been given that both French and German vital statistics would be better found than our own. In fact they are worse found. The reason seems to be that if we do happen on an official who is eccentric enough to be an enthusiast we let him have his head provided, of course, that he is sufficiently eccentric not to demand any generally coveted

honour or a large salary. Again, if a man who will not be blamed for letting things slide does not let them slide we may not praise him, but we shall not obstruct him much. English vital statistics have profited immensely from these national habits. When we began census-taking the supervision of the work was entrusted to a clerk of the House of Commons—a highly paid official with a good deal of his own proper work to do. Nobody would have said anything if he had taken the job very easily. In fact the official—John Rickman, Charles Lamb's friend—took it very seriously indeed and laid excellent foundations. Thirty-five years later, when we instituted national registration of births and deaths, luck favoured us again. This time it was not a highly paid and slightly pompous official whose real work had nothing in the world to do with statistics who made good; it was a young, ill-paid medical man whose official status was very different from that of a clerk of the Honourable House of Commons. It was a Mr. Farr, a gentleman of the medical profession, for whom the friendly patronage of a court physician had secured the post of Compiler of Abstracts in the new General Register Office. He laboured forty years, and eventually secured that reward usually reserved for industrious clerks—as Mr. Lytton Strachey calls it—the C.B. The nation secured a system of vital statistics which the logical French and the tidy Germans will continue to envy for some generations.

The steps by which the present position was reached are carefully recorded in the handbook. The General Register Office is not architecturally a very imposing building; the Annual Reports of the Registrar General do not seriously compete with the daily newspapers for the custom of those who travel hopelessly and

arrive unpunctually by the Southern Railway. Yet the General Register Office and its works deserve more reverence, and are the objects of more admiration upon the Continent and even in the United States of America, than most Englishmen know.

A.M.A. AND B.M.A.

The Journal of the American Medical Association, in its issue of August 8th, published an editorial article, very cordially worded, congratulating the British Medical Association on its new home, on the recognition accorded by the head of the State by the visit of the King, accompanied by the Queen, on July 13th, and on the appreciation and approval of the Association's aims and objects expressed in the King's reply to the Address presented to him before he formally declared the building open. The constitutions of the two Associations present many points of resemblance, the differences are to be traced in the main to differences in the political constitution of the two countries. The aim of the two is identical—both, to use the words of our contemporary, have "stood always for service to scientific medicine and to the public."

HARVEY'S DISCOVERY OF THE CIRCULATION

In the Harveian Oration delivered on July 10th to the Edinburgh Harveian Society, Dr. P. McBride asks the question, "Why did Harvey discover the circulation?" We take it that, although he put his question in this form, Dr. McBride did not mean to inquire into Harvey's motives, but rather into the concatenation of personal qualifications and favouring circumstances which rendered Harvey's attempt successful. A clear and logical mind, well stored with the anatomical knowledge of that day, and a disposition to see for himself rather than to trust to the statements of others, and a consequent reliance on experiment rather than speculation—these were the main characteristics which enabled him to make his great discovery. Dr. McBride perhaps strikes too much of the dangers incurred in the fifteenth and sixteenth centuries by those who would pry into the secrets of nature. As long as the inquirer kept clear of metaphysics and theology he ran little or no risk of getting into trouble over any anatomical researches or speculations. The father of scientific anatomy, Vesalius, was the trusted attendant of the orthodox Emperor Charles V. It is true that Galileo suffered for contradicting a meaning commonly attached to a biblical statement concerning the earth, but, fortunately, physiological investigators did not run the same risk, for the statements on anatomy and physiology in the Bible are not explicit. Servetus might have advanced the most revolutionary and unorthodox theories of the circulation and escaped scot-free, but the moment he touched the Trinity he was lost. Dr. McBride contrasts the fate of witches in Scotland (and afterwards in England) with the good fortunes of astrologers, which may be accounted for by the relative repute of black and white magic. No doubt Harvey, as he himself said, owed a great deal to his frequent and repeated vivisections, but Galen and Vesalius practised vivisection before Harvey was born without making great discoveries in physiology, in the seventeenth century nobody entertained any objection to the practice. Even cruelty to animals was hardly objected to. Hogarth in the following century, in his *Stages of Cruelty*, depicts scenes of cruelty to animals, but his implied condemnation is on account of the indifference to suffering in mankind which follows on wanton infliction of pain upon brutes. Harvey's views were not accepted by all contemporary physiologists, and they resorted to every argument that they could find against them. But bitter as some of

them were, no one ventured to stigmatize his opinions as not new, indeed, the chief objection to them was their novelty. We are inclined therefore, to differ somewhat from Dr McBride in that we would ascribe little importance to the ripeness of the time for Harvey's discoveries and nearly all to the character and intellect of the man, which impelled him to persevere and enabled him to brush aside prejudices and to draw sound conclusions from facts. In the words of Professor William Stirling¹ Harvey did more than discover the circulation of the blood; he demonstrated by the experimental method that the blood moves in a circle; that the movement of the blood is due to the mechanical action of the heart as a pump; that systole is an active contraction of the heart and diastole a passive act of dilatation. He gave a true theory of the pulse. For all time he set the method—namely that of experiment and induction—which has led to all modern progress in physiology."

SPECIAL LIBRARIES AND INFORMATION BUREAUX

In September 1924, a small conference was held at High Leigh, Huddersdon at which a group of those interested in agencies for the collection, treatment, and distribution of information discussed some of the many problems involved in their special work. The conference was called at short notice, in the holiday season, and without any extensive advertisement, and the discussions were informal. Nevertheless it aroused keen interest, not only amongst the organizations engaged in industrial research, members of which were primarily responsible for its initiation, but in a far wider circle including scientific, educational, social, political, and commercial bodies of varying scope and character. There was a general demand for the creation of machinery to carry on the work of co-ordination suggested by the conference, and a standing committee was appointed for the purpose, under the chairmanship of Mr. J. G. Percie of the British Cast Iron Research Association, and with Mr. A. F. Ridley, F.L.A., librarian of the British Non-Ferrous Metals Research Association, as honorary secretary. On this committee the British Medical Association is represented by its Intelligence Officer. As a result, a body known as the Association of Special Libraries and Information Bureaux has come into being, and arrangements have been made for a second conference to be held at Balliol College, Oxford, during the week-end from September 25th to 28th. In the interval the standing committee has done some very useful work. It has secured the financial support of the Carnegie United Kingdom Trustees, has appointed an organizing secretary, published an extremely interesting report of the 1924 conference, with a foreword by Sir Philip Cunliffe Juster, President of the Board of Trade, and begun the collection of data for the issue of a directory of special libraries and information bureaux in Great Britain. The association covers the field of what may roughly be termed the special library movement, the development of which, already far advanced in America, is only beginning in this country. Its primary object is to co-ordinate, in the general interest, the many collections of specialized information already in existence, to promote the formation of new libraries where this seems necessary, and to act as a clearing house for the existing sources of information, and a medium of intercommunication between those engaged in their development and use. Its programme includes the indexing of sources of statistical and other data, co-ordination of abstracting services for scientific and technical societies, an increase in the accessibility of periodical and other literature in national and local centres, registration of classified panels of translators for the service of particular industries, sciences,

and arts, and an increased provision of photographic and other copying apparatus. The problem of avoiding waste of energy in the collection of data by securing the readiest possible access to all sources of information is one which in the multiplicity of existing agencies for investigation touches the scientific and the social order at least as closely as the industrialist. Any step towards its solution is welcome. We may recall the effort in this direction made by the British Medical Association by the publication of the list of periodical of medicine and the allied sciences in British libraries compiled under the direction of Professor R. T. F. C. P. R. S.² This list shows the libraries in which periodicals can be found in London, Cambridge, Edinburgh, Glasgow, Liverpool, Manchester, and Oxford classified under the countries in which they are published. We shall wait the report of the forthcoming conference with interest. Full information as to the activities of the Special Libraries Association and conditions of membership can be obtained from the organizing secretary, Mr. W. Keeling, 38 Bloomsbury Square, London W.C.1 to whom early application for accommodation at the conference should be made.

THE HOME AMBULANCE SERVICE

During the second quarter of this year the ambulance of the Home Service Ambulance Committee of the Order of St. John and the British Red Cross Society carried 18,026 cases exclusive of pensioner patients carried to Queen Mary's Hospital, Roehampton, they numbered 7,512. The committee now has 241 ambulance stations in the country and 34 other stations affiliated with it. Three new ambulance stations were established (Drif, Iodmorden and Woodford) two stations were transferred the one from Colyton to Hounston and the other from Newport (Mon.) to Llanelli. Three other stations were closed, but one of them only temporarily. The funds at the disposal of the committee render it necessary to limit the fitting up of the ambulance cars to what is absolutely essential to secure a reasonably comfortable vehicle for the removal of patients. In districts where funds can be found locally larger and more elaborate ambulances are provided, in this way very fine ambulances have been secured by Norwich and East Grinstead and others—for Jarlow and Southsea—are in the builders' hands. Thanks to the generosity of Mr. and Mrs. Ellis and Mr. Griffin, an extremely well built and thoughtfully designed ambulance has been presented to the committee for use at Havwards Heath. During the quarter the liaison officer, Major Piget, visited ambulance stations in North and South Lincolnshire, the North, East, and West Ridings of Yorkshire, Durham, Northumberland, Cumberland, and Westmorland. Such an extensive tour, which included some forty ambulance stations, afforded an opportunity for forming an estimate of the value of the service and of the manner in which the work is carried out. Major Piget was able to report highly of the efficiency of the ambulance service generally, and of the benefit it is proving to the community. From the members of the medical profession the officers of local authorities and from those concerned with the working of the service, the most gratifying testimony was received as to the great advantage that has accrued from the setting up of an ambulance service available day and night for the removal of cases of accident and illness. The work in some of the northern counties is not easy, owing to the severe gradients and the difficulties of approach to houses in moorland districts. Here, as in other parts of the country, road accidents are increasing and sometimes the demand on the ambulances is very heavy. As an instance the disaster at Dibbles Bridge on the Yorkshire moors may be mentioned, when a charabanc

carrying a party of twenty five persons got out of control on a hill, crashed through the bridge at the bottom, and fell down the rocky bank to the river below. Seven of the passengers were killed outright, and sixteen severely injured. As soon as a telephone message could be got through to Skipton (fifteen miles away) the ambulance, with a first-aid party, started and brought the injured people to the Skipton Hospital. This entailed four double journeys, covering 120 miles, which were completed without a hitch. This is good proof of the efficient state in which the ambulance was maintained. This is true of the majority of stations; it is noted that when ambulances are housed at fire stations they are particularly well looked after, but that in commercial garages also the proprietors take great care of the car and do not regard it solely as a commercial undertaking. At one place visited where the ambulance car was undergoing overhaul at the expense of the local committee, it was found that the body of the ambulance was being thoroughly repaired and repainted at the expense of the garage proprietor as his contribution to the service. Only in a small minority of the stations could any complaint be made as to the condition of the ambulances, in these it was generally the body-work or the springs which showed sign of neglect.

THE PROFESSIONAL CLASSES AID COUNCIL

THE report of the Professional Classes Aid Council for 1924-25 shows an increase in its activities. More adequate help has been given than in recent years, whilst at the same time administrative expenditure has been slightly reduced. Two thirds of the grants made are for the education of children or the training of young adults. This has been a great relief to harassed parents, and is of great future value. Where grants are made for the assistance of particular persons the aim is always to help the recipients to reach independence, and in this there has been much success. At present the finances of the society only allow it to deal with cases of the greatest difficulty and those which require a maximum of work and administrative expense. More money would enable it to deal with

those inexpressibly sad cases of elderly people whose power of self-support has failed, and to whom only a pension is of real value. The society has on its council representatives of all professional societies, including the British Medical Association. Its address is 251, Brompton Road, S W 3.

REPETITIVE WORK IN INDUSTRY

THE Industrial Fatigue Research Board of the Medical Research Council has published a report¹ on an industrial investigation of the effects produced on four girls of different degrees of intelligence by work entailing incessant repetition. The results of introducing various rest pauses into the work was also studied and a comparison was made of time-rate and piece-rate remuneration. The repetitive work consisted of cross stitching with a coarse silk thread on canvas squares. The output was measured by the number of stitches; the work could not become automatic, as it required constant attention. The girls worked for six hours a day, in two spells of three hours each, for four days a week. It was found that the two most intelligent girls were the most variable workers, and that the girl with subnormal intelligence showed a steady improvement in ability. The investigation thus supported the view commonly held that the highly intelligent individual is not suited to repetitive work, and it is suggested that it might be possible to distinguish these types in children while at school, with a view to preventing the individual from engaging later in unsuitable occupations. The introduction of rest pauses did not benefit the output, but it is pointed out that with an eight hours' day and a

week of five and a half days the results might have been different. Comparing the output of the time-rate and piece-rate bases of payment for output, it was found that under piece-rate conditions the output curves were on a higher daily level in all cases, but that with workers of approximately equal capacity the variation about the average was less. Competition between the more equally skilled girls aided output and occurred more frequently under piece-rate conditions, but the output of the less skilled workers seemed to be reduced owing to discouragement. Emphasis is laid on the importance of this point in the consideration of the many psychological problems raised by term work in industry. Term work may increase output in certain circumstances, but an effective term should consist only of workers of approximately equal abilities. Failing this the faster worker will be retarded by the presence of the slower, and the output of the latter will decrease because she is discouraged by the presence of the former, thus a vicious circle is created. The good effects of changing from time-rate to piece-rate conditions were more marked in the more intelligent and variable types of worker.

VERMOUTH

VERMOUTH wine has recently become a common article of commerce in this country, although it has been popular for many years on the Continent as a stimulant and an aperitive. Its use appears to be extending, and it is taken now not only with soda as a mild alcoholic beverage, but forms the basis of most cocktails. Recipes for its preparation are numerous, but the following will serve as a sample.

Wormwood, 4 oz, tansy, 4 oz, gentian, 2 oz, angelica root, 2 oz, blessed thistle, 4 oz, calamus aromatics, 4 oz, elecampane root, 4 oz, centaury leaves, 4 oz, germander leaves, 4 oz, nutmegs, 15, oranges sliced, 6, alcohol of 85°, 9 pints, sweet white wine, 20 galls, macerate fifteen days and filter. It will be seen from this that several of the plants contain principles which excite the cerebral cortex, especially as this is the case with wormwood and tansy, which contain a principle, thuyone, which is isomeric with camphor and which causes epileptiform convulsions in sufficiently large doses just as camphor does. It is for this reason that France has forbidden the drink absinthe, which is made largely from wormwood and contains a varying amount of thuyone. Over-indulgence in absinthe induces sleeplessness, a general condition of unrest, and sometimes vomiting. Later vertigo and tremors, especially of the head and tongue, are a foreshadowing feature, culminating in epileptiform convulsions in which consciousness is usually lost and clonic convulsions occur. The fits recur at short intervals. Recovery is complete if the habit is broken in the early stages. Besides wormwood and tansy, several other essential oils excite the cerebrum especially nutmeg, and from time to time cases of convulsions following the eating of nutmegs have been recorded in the *BRITISH MEDICAL JOURNAL*. Vermouth is thus a mild alcoholic beverage, containing about three-quarters as much alcohol as is present in sherry, but its action is fortified by thuyone and other principles from essential oils, and it is no doubt these substances which induce the exhilarating effects of the beverage. It should not, however, be placed in the same category as absinthe, although both contain the same principles, the relationship between these two drinks may be compared with that between a light wine and a spirit.

THE HOSPITALS OF LONDON

THE report of the King Edward's Hospital Fund for London for the year 1924 is a document of great interest. It contains general particulars of the work and accommodation of 113 hospitals. There has been a marked expansion of work. Beds have increased by 350 as compared with the

¹ Part No 39. London: H.M. Stationery Office, 1925. Price 2.6d net.

previous year, the average occupied beds by 360, new in-patients by 9,000, new out-patients by 60,000, and the total out-patient attendances by 204,000. The increase of beds is noteworthy in connection with the report on hospital accommodation by the Voluntary Hospitals Commission. Since 1913 there has been an increase of 1,620 beds and 760 average occupied beds. No reason is given for the increase in out-patients, and it would be interesting to know in what type of hospital or department this has occurred. The income for 1924 received no special augmentations, and is therefore comparable with previous receipts, the total was £2,918,000, an increase for the year of £58,000, or 2 per cent. Income from investments increased, that from subscriptions and donations fell slightly, patients paid more, legacies were about the same, 34 per cent of the total ordinary income was "earned"—that is, received as payments by patients or public authorities. Expenditure was less than income, but had increased for all purposes except establishment charges. There follows a series of most instructive comparative tables showing the income and costs of the various hospitals. Those of the same type are classed together—for example, hospitals with medical schools, ophthalmic hospitals, children's hospitals, etc. It is therefore possible to compare these hospitals. There are some curious differences in apparently comparable hospitals for which no explanation is suggested. For instance, we note that in the hospitals with medical schools the average number of days each patient was resident works out at the London at 14.35, whereas it is 23.73 at St Bartholomew's and 28.63 at Westminster, and the average for all is 19.51, amongst large general hospitals without medical schools the figure for the Royal Northern is 17.54 and for the London Temperance 31.76 with an average for all of 22.21. The reasons for wide differences such as these should be ascertained. In one point the report is much behind the times, for it writes of the Ministry of Health as the "Local Government Board."

WHAT TO DO WITH OUR BOYS

THIS is something like it was, if we remember correctly, the title of a book published some years ago. We forget whether emigration to one of the Dominions was among the careers suggested by the author, but we assume that it was, and if it was to be recommended in the past still more is it to be considered in the future. A very favourable opening for a lad from 15 to 17½ years of age, who is inclined to an outdoor life, is now offered by agricultural scholarships in New South Wales offered by the Fellowship of the British Empire Exhibition. The right to nominate to these scholarships was determined by the results of a ballot, and among those who drew lucky numbers were Mrs C. Paterson, the wife of Dr William Paterson, honorary secretary of the Willesden Division, and Dr A. Baldie, a member of the Association residing in Kensington, who has nominated a son of the late Dr Denis Flynn of Cork. A fortnight ago a Current Note was published stating that a vacancy had unexpectedly occurred, and that Mrs Paterson had offered to nominate a suitable boy who was a relative (or orphan) of a member of the Association. The offer is still open, particulars should be sent to the Medical Secretary, British Medical Association House, Tavistock Square, London, W.C.1. The lad, as has been said, must be between 15 and 17½, and of good character and physique. He must pass the tests, including the medical tests imposed by the Australian Government, and must be approved by the Central Committee of the Fellowship of the British Empire Exhibition. A successful candidate is given a free passage and one year's training at an agricultural college in New South Wales, and will afterwards be placed in suitable employment on the land

with a view to his acquiring ultimately a farm of his own. A better start for a suitable lad in Australia could hardly be imagined.

AUSTRALASIAN MEDICAL CONGRESS OF THE BRITISH MEDICAL ASSOCIATION

DUNEDIN, NEW ZEALAND, 11 FEBRUARY, 1927

The Second Session of the Australasian Medical Congress (British Medical Association) will be held in Dunedin, New Zealand, from February 2nd to 9th, 1927, in the new Medical School at present under construction, and will be opened by Sir Charles Fergusson, Bt., Governor-General.

The President of the Congress is Dr J. L. Barnett, C.M.G., Lecturer in Professor of Surgery in the University of Otago, and he will be assisted by an executive committee including Dr D. J. Cornhill-Jones as honorary treasurer, Dr W. P. Gowland as honorary general secretary, and Dr A. M. Dorman as honorary associate secretary.

The scientific proceedings will be conducted in twelve sections as shown below. Provision will be made for a trade exhibition of books, instruments, drugs, etc.

Further particulars will be given at a later date but those seeking further information in regard to the Congress and firms desirous of co-operating in this exhibition are requested to communicate with Dr W. P. Gowland, honorary general secretary, Australasian Medical Congress, Dunedin, New Zealand.

PRESIDENTS AND VICE-PRESIDENTS OF SECTIONS

Medicine

President Professor A. I. Mills (N.S.W.)
Vice Presidents Dr I. S. Latham (Vic.) Dr D. Gifford Croll (Bt.) (Q.) Dr C. J. Ch. de Crespigny (S.A.) Dr R. C. Mearns (W.A.), Dr Gibson (Wellington, N.Z.)

Surgery

President Dr B. Kilgallon (Vic.)
Vice Presidents Professor F. P. Sanders (N.S.W.) Dr F. A. Hadley (W.A.) Dr I. Sandford Jackson (Q.) Mr A. M. Cudmore (S.A.) Dr Acland (Canterbury, N.Z.)

Obstetrics and Gynaecology

President Dr I. W. Dunbar Hooper (Vic.)
Vice Presidents Dr I. C. Windward (N.S.W.) Dr D. P. Clement (W.A.) Dr W. A. Vero (S.A.) Dr I. Marshall Allan (Q.) Dr Jellett (Canterbury, N.Z.)

Pathology and Bacteriology

President Dr C. H. Mollison (Vic.)
Vice Presidents Dr J. I. Dunlop (Q.) Dr I. Dale O'Brien (W.A.) Dr A. H. Lebbitt (N.S.W.) Dr A. B. Pearson (Canterbury, N.Z.)

Internal Medicine

President Dr Huxley Sutton (N.S.W.)
Vice Presidents Dr R. W. Cleto (Q.) Dr R. C. Atkinson (W.A.) Dr T. W. Smelan (Vic.)

Ophthalmology

President Dr A. M. Moynan (S.A.)
Vice Presidents Dr C. C. MacLeod (N.S.W.) Dr J. I. Rudall (Vic.) Mr J. Lockhart Gibson (Q.) Dr D. D. Paton (W.A.) Dr J. Lenwick (Auckland, N.Z.)

Otology, etc.

President Dr R. H. Pullen (S.A.)
Vice Presidents Dr S. A. Ewing (Vic.) Dr W. C. Mansfield (N.S.W.) Dr H. B. Gill (W.A.) Mr W. N. Robertson (C.B.E.) (Q.) Dr J. Hardie Neil (Auckland, N.Z.)

Neurology

President Sir John Macpherson, C.B. (N.S.W.)
Vice Presidents Dr W. Ernest Jones (Vic.) Professor J. P. Lawson (Q.) Dr D. M. McWhane, C.M.C. (W.A.) Dr Chisholm (Canterbury, N.Z.)

Diseases of Children

President Dr A. Jefferys Turner (Q.)
Vice Presidents Mr H. D. Stephens (Vic.) Dr J. M. Gill (N.S.W.) Dr R. H. Crisp (W.A.) Sir Truby King (Wellington, N.Z.)

Naval and Military

President Dr G. W. Barber, C.B. C.M.C. D.S.O. (W.A.)
Vice Presidents Dr R. M. Downes (Vic.) Dr J. S. Purdy, D.S.O. (N.S.W.) Dr G. W. Macintyre, D.S.O. (Q.) Sir Donald McGavin (Wellington, N.Z.)

Orthopaedics

President Dr N. D. Royle (N.S.W.)
Vice Presidents Dr W. Kent Hughes (Vic.) Dr H. S. Newland, C.B.E. D.S.O. (S.A.) Dr A. J. Jett (W.A.) Dr A. A. McLean (Q.) Dr Wylhe (Wellington, N.Z.)

Radiology

President Dr S. S. Argyle, M.L.A. (Vic.)
Vice Presidents Dr H. L. Scar (N.S.W.) Dr A. J. H. N. Let (Q.) Dr H. C. Nott (S.A.) Dr D. I. R. Smith (W.A.) Dr N. Macdonald (Auckland, N.Z.)

We are indebted to Dr Noel R Rawson of Whitley Bay, Northumberland, for sending us an extract from Gibson's *Lambles in Europe* in 1839, describing the annual meeting of the Provincial Medical and Surgical Association, the precursor of the British Medical Association, it will, we believe, be read with interest by members to day.

We learn from an article by Dr Francis R Packard in the *Annals of Medical History* for June that Dr William Gibson was born in Baltimore in 1788, attended St John's College in Annapolis and Princeton College, and took a course in the University of Pennsylvania, but did not graduate there. Instead he went to Edinburgh, where he received the degree of M.D. in 1809. In 1811 he was active in establishing the medical department of the University of Maryland, in which he was professor of surgery until 1819, when he succeeded Physick in the corresponding chair at the University of Pennsylvania. Gibson, Dr Packard says, was a fine teacher, and a bold and dexterous operator, and possessed of considerable artistic ability. He retired from his chair in 1855 and died in 1868. He seems to have been an enterprising traveller, for while in Edinburgh he and some of his friends chartered a vessel, sailed to Spain to see something of the battle of Corunna (January 16th, 1809). In 1815 he was again in Europe and was a slight wound from a stray bullet. The full title of his book is *Sketches of Prominent Surgeons, Physicians, Medical Schools, Hospitals, Literary Personages, Sec.* etc. etc. it was published in 1841, and the following is the text of the extract Dr Rawson has made.

ANNUAL MEETING IN LIVERPOOL, 1839

Having formed the acquaintance and enjoyed the society of the most eminent of the London faculty, I felt a natural desire to see the provincial surgeons and physicians, many of whom, in almost every town and village of the kingdom, had attained distinction and were by then writings more or less known abroad. How to accomplish the purpose, however, I was much at a loss for, to proceed regularly from town to town with the view of prosecuting them up would have consumed so much time as to preclude the possibility of attaining my end. Whilst reflecting on the subject I called at Sir James Clark's and luckily met Dr Forbes of Chichester who in course of conversation mentioned that the 'Provincial Medical and Surgical Association' would shortly meet at Liverpool and gave me a pressing invitation to attend, assuring me that I should there see almost every eminent country practitioner of England, Ireland, and Scotland. This was too good an opportunity to be lost, and I had accordingly great pleasure in joining that illustrious body on the 25th of July, 1839.

This Association was established at the suggestion and chiefly through the exertions of Dr Hastings of Worcester in 1832—with the view of concentrating all the provincial medical and surgical talent, and directing it towards the investigation of disease, the diffusion of useful information through hospital reports, dispensaries, and private practice the laws of epidemics and their connexion with peculiarities of climate and soil or habits of the people, the laws of statistics, meteorological and botanical inquiries in reference to topographical information, the advancement of medical jurisprudence but chiefly towards the maintenance of the honour and respectability of the profession generally in the provinces, by promoting friendly intercourse and free communication of its members and by establishing amongst them the harmony and good feeling which ought ever to characterize a liberal profession.

¹ An address delivered at the first meeting of the Provincial Medical and Surgical Association by Charles Hastings M.D.

² This declaration was repeatedly made to me by the one who could afford to be candid.

Upon the foundation, thus laid, a most important institution has been reared, one calculated to exert immense influence, not only over the English provinces and the metropolis itself, but upon the medical literature and practice of almost every nation under the sun, for the great body of British physicians and surgeons, residing in the country or in country towns, being remarkable for their intellectual education and classical attainments, having the full advantage of well regulated and sufficiently large hospitals, and, withal, not so overwhelmed with the crowds of patients that infest and besiege the most eminent of them as in London brethren, a large proportion of whose time is consumed in riding slowly through streets choked with vehicles of every description, and so thronged by foot-passengers as to render progression extremely difficult, and sometimes and to the disadvantage of patients thus subjected to the advice and prescriptions of men so fatigued and worried as to be unable, confessedly, to remember the cases presented to them from day to day, or the remedies ordered for their relief, are acknowledged to be, as a body, the most learned and efficient practitioners in the kingdom. But if evidence were wanting to establish the fact, the numerous and voluminous writings of provincial men, though issued generally from the London press, would be amply sufficient to substantiate their claims. If such, however, have been the merits, almost from time immemorial, of the profession in the country towns where there was no connecting link to bind them to each other, or standard under which to rally and fight their way to the heights of fame for want of strength into metropolitan arms, how much more may now be expected from such professional combatants, who inspired by the enthusiasm that springs from the love and pride of native soil, heightened by the all-pervading influence of interest and community of design? That the anticipations of the few who assembled under the auspices of their enlightened and enterprising leader have been amply realized by the treasures so bountifully thrown within the last eight years, into volumes of 'Transactions of the Provincial Medical and Surgical Association,' the official list of professional worthies, from every nook and corner of 'English, Scotch, and Irish land,' there cannot be the smallest doubt. Of most of these it would be impossible to speak, but the names of Hastings, of Barlow, of Forbes et alius, are too intimately blended not only with the 'Provincial Association' but with the medical literature of England, to be passed over in silence.

"Dr Hastings is a native of Worcester, about 45 years of age, rather tall and slender, and but for a halt in his gait, the result probably of some accident might be said to possess an eminently handsome figure and carriage. His countenance is open, cheerful, and jovious, and remarkably stranger would instantly ask 'What kind hearted intelligent-looking man is that—so full of activity, enthusiasm, and humility combined?' I saw him for the first time in the crowd of medical men assembled in the hall of the 'Liverpool Medical Institution'—a splendid stone building of the Ionic order, designed by Rumphing—where the Association held its meeting and immediately exclaimed to my friend, Dr Smith of South Cheshire, 'where that man may be but am deceived if he does not play an important part in this assembly. Upon entering a few minutes after, the lecture room, our eyes were instantly turned to a magnificent full-length portrait of the person in question and beneath to a large superbly executed mezzotint of the same picture, with the name of Charles Hastings, M.D. upon its margin. Upon inquiry we found that the portrait had been painted at the expense of the society, and presented to the family of Dr Hastings, in commemoration of his very important services and the affectionate interest evinced by him upon all occasions for the welfare and happiness of his fellow-members. The point too we were told had been subscribed for, at an

additional expense, by numerous members anxious to possess some memorial of the man for whom they all entertained the highest respect and admiration. But notwithstanding the extraordinary hold thus possessed by Dr. Hastings on the affections of the society with a modesty and humility which reflect great honour upon his heart, it was soon discoverable that his services were the spontaneous offerings of disinterested benevolence, actuated solely by a deep and abiding sense of the duties he owed the profession, by disregarding the dictates of ambition which so often prompt the best of men to efforts of personal aggrandizement. Influenced by such feelings he has continued from the first to occupy the humble but important and arduous office of secretary to the Association instead of aspiring to the more dignified and elevated seat of president which he conceives should be reserved for the exclusive use of such elder members as are fully entitled to the honourable designation 'elder and venerable men.' There are occasions, however, when Dr. Hastings is drawn from the retirement he counts, by the recommending voice of the society that leave him no chance for escape. When he is called upon to enter the lists with disputants and discuss the merits of some important question, or to exercise his solid judgment upon points that try the understandings of his associates, or when selected to preside over the 'feast of reason and flow of soul' inspired by the splendid repast that crowns the festive board and terminates each annual meeting of the Association, when he is suit to make, in a strain of manly eloquence, such powerful appeals to the head and to the heart as never fail to carry conviction to the minds of his delighted hearers and to attach them, body and soul to his person and plans. Various demonstrations of the kind were afforded me, during debate at the regular sittings of the Association but it the public dinner served at the town hall where four or five hundred members, citizens and strangers assembled and listened to an extemporaneous address by Dr. Hastings is chairman upon the occasion the most thrilling, sensations were created in every bosom by the delicate chords touched by a master hand as it played over, with exquisite grace and felicity of expression, the various symphonies best adapted to warm the heart, enlighten the understanding and excite the ardour and enthusiasm of all present. It was then too he won golden opinions from every stranger by a display of unbounded liberality towards cultivators of science and particularly the science of medicine over the whole earth. It was then he awakened the sensibilities of every American present when he spoke of 'a country endeared to Britain by the ties of consanguinity, of a country in which the same language was spoken over a vast extent of territory, of a country of brethren towards whom England looked as her sons and descendants and for whom she entertained the feelings which ought to exist between parent and child' when he said he was glad to find that Americans visited the homes of their ancestors and mingled with their brethren on that side of the Atlantic and particularly glad they had upon that and other occasions honoured their medical Association by their presence, hoped they would repeat their visits, and others join with them hereafter from the same great country in celebrating their anniversary, and in cementing a bond of union that would prove equally honourable and beneficial to both and above all, that members of the University of Pennsylvania, so long and so favourably known would unite with them in harmony and good fellowship, and assist in extending the boundaries of medical science to the remotest corners of the earth. I should not have done justice to my country or to my own feelings, or to our University, had I remained silent after the loud, enthusiastic and reiterated cheers which followed that and some other portions of Dr. Hastings' address and trust that the sentiments and views I had then the honour to present, feeble as they were, and must have been after the waving of a magician's wand, may have served at least the salutary end of drawing closer and of strengthening the bond of union between the two great nations. A meeting which ought ever to exist between the two nations, and which ought to be the result of one year's training of professional men, who not only visit each other but also confer the same day the day on the land

my humble name to the list of their own distinguished members.

Independently of his connexion with the Provincial Association Dr. Hastings enjoys high reputation as a practitioner, and is not less distinguished as a fine scholar and classical writer, as is sufficiently proved by his valuable work on *Inflammation of the Mucous Membrane of the Tongue* and by various essays in the different periodical publications of the day.

Of the venerable Dr. Barlow of Bath who the year before had filled the honourable office of president of the Association I cannot but speak in terms of high commendation. Though approaching in appearance and garb, to the primitive simplicity of a Quaker or Methodist, there is an energy displayed in his fine regular features in connexion with a bald head and such development of the anterior lobes as a physiologist would associate with extraordinary moral and intellectual qualities, conjoined with uncommon vigour of frame, in shape of short well knit joints and bony muscles, it would induce even a careless observer to conclude at first sight, that he was no common man. Such was my own conclusion before he opened his lips, and by the time he had uttered a dozen words in returning thanks to the Association for the compliment paid in selecting him as last year's chairman, I was fully prepared to believe that few men could be found in that, or any other assembly, superior in vigour of intellect, clearness of conception, consistency of views, and dignity of mind and demeanour. And I was not mistaken for, afterwards, during the whole of the debate there was displayed a degree of intellectual composure and serenity, with quickness, sagacity and even sharpness—so visible in his piercing black eyes mixed with it but so tempered at the same time by kindness of manner and benevolent expression, as to impress irresistibly his hearers that he was not only a very sensible, highly cultivated and learned man, but a good honest truth-seeking plain dealing excellent Christian. By birth I believe Dr. Barlow is an Irishman. Certainly he ought to be judging from his short, compact figure, square shoulders and muscular powers. But he has not a particle of brawn nor any of that mercurial moisture of the eye and comeliness of countenance that stamp the Irishman on the contrary his speech and whole demeanour afford apparent evidence of the regular John Bull. His writings, by which he is well known in Europe and in this country consist of a work on pathology, published twenty years ago in essay on ovarian dropsy, another on the effects of Bath waters, and of various papers in different periodical publications.

Of Dr. Forbes of Gloucester whose name I have already mentioned it gives me peculiar pleasure to speak, not only on account of the great personal civility experienced at his hands in being made known, through his kindness to most of the distinguished members of the Provincial Association, and through his instrumentality, in the most flattering way, elected a member of that society, but for the rank he deservedly holds in the profession, to which he has raised himself by talents of very high order, conjoined with such excellent qualities of the heart as have endeared him to society and, above all for the liberality and good feeling he has uniformly displayed in speech and action, and in his numerous and diversified writings towards his American brethren and their country by using upon many occasions such language as the following. 'The love of science is too pure and elevating to permit those imbued with it to be contaminated by the narrower and baser feelings so mischievously encouraged by too many writers who have visited America and who have composed books apparently without entertaining any views worthy of the people of that enlightened country.'

Dr. Forbes is a tall stout, broad shouldered, powerful man, and looks as if he could not only endure great hardship and labour but judging from his quick step and activity would take great delight in encountering it. His head is large and well formed, his complexion healthy and ruddy and his features unmarred and agreeable. By birth he is a Scotchman, but has lived for a long time in England, first at Penzance, or the Land's End, on the climate of

which he has published a valuable dissertation, and subsequently at Chichester, where he still resides, enjoys extensive private practice, and has control of a well regulated infirmary. He is, moreover, the translator of Lenné, the author of an excellent work on medical bibliography, and one of the editors of the *Cyclopedia of Practical Medicine*. But he is better known at home and abroad by his valuable contributions to the *British and Foreign Medical Review* or *Quarterly Journal*, edited by himself in conjunction with his distinguished friend Dr John Conolly, formerly of Warwick, but now of Haver, near London, than by any other productions. Of this work it would be out of place to speak, further than to say that of all the foreign reviews, it is incomparably the best, being conducted on the fairest and most liberal principles, filled with details, theoretical and practical, of the most useful and interesting description, and breathing of a spirit of independence such as every educated and high minded physician must cordially approve, and as such deserving extensive circulation throughout every part of our extensive country.

Although no small share of the attention of the Provincial Association was directed during its attendance to medical reform and various other professional interests, general and local—the discussion of which drew forth the pen of numerous members, some of whom were not remarkable for grace of elocution, whilst others displayed in the extent of information, a tact and logical precision in argument, and in eloquence, combined with courtesy and respect towards opponents seldom met with in mixed assemblies—yet the highest degree of interest, it appeared to me, was elicited by the delivery of the Retrospective addresses, two of which we read annually, by distinguished members appointed previously to the task—the one embracing medicine, the other surgery, with all their concomitant relations, to associate sciences. These addresses upon all the occasions referred to, were delivered by Dr Synonds of Bristol, on medicine, and Mr James, of Exeter, on surgery.

Dr Marshall Hall who for the last twenty years has attracted so much attention by his voluminous practical and physiological writings was a close attendant upon the meetings of the Provincial Association. He is a man of striking appearance and of a list of fortunes so decided and remarkable as not to be overlooked even in a crowd. He commenced his career as a surgeon at Nottingham, but afterwards removed to London, where he is chiefly known as a physician, and a lecturer in St Andrew College, associates of unquestionable native talent and originality, joined to unflinching application, Dr Hall has pushed his way to eminence by his own individual merits and exertions—without any of the adventitious aids and trinkets which men of limited capacity and scanty requirements so often resort to, successfully, to blind and unbookish the public. I can before he graduated and whilst a student at the Royal Infirmary of Edinburgh he delivered lectures on diagnosis, and published reviews and essays in periodical journals. From that period to the present time, a space of nearly thirty years he has been a most diligent and laborious cultivator of almost every branch of medical science, as his works, which speak for themselves amply testify. It was with great satisfaction, therefore, I formed the acquaintance, slight as it was, of such a man.

"I cannot close my account of the Provincial Association and its prominent members, without referring to the efforts made individually and collectively by that great body, to accomplish three kind of important purposes—equally dear and interesting, as they ought to be, and will prove, no doubt, in time to ourselves and the profession at large, throughout the world. To wit: the extent, and evils of the profession to consider the nature, and evils of quackery, and to give to the profession, through the medium of reform, a sound and legal constitution." It would be impossible within the scope of my present undertaking, to enter into the details necessarily embraced by this important and interesting subject, and will therefore mention that immense efforts are making by the Provincial Association, directed by such men as Birlow Hastings Forbes

and by their distinguished associates in Ireland—Crimichael, M'Donnell, Osborne, Munsell, and others through the *Dublin Medical Press*, and by the London University, as must at no distant day bring about a revolution in the medical affairs of Britain, which may, eventually, extend to the whole world."

New Zealand.

MEDICAL RESEARCH

The past year has been marked by the special interest that has been taken in medical research. The Minister of Health of New Zealand (Sir Mun Pomare) has shown particular interest in keeping New Zealand in the foreground in matters affecting the public health. The Health Department is at present engaged on several separate investigations. The high incidence of goitre has for some time been the subject of considerable discussion, and the Government came to the conclusion that this malady might, if unchecked, assume such dimensions as to constitute a serious problem in public health, as it is present the everywhere in Switzerland. Knowledge of the means where goitre is endemic was provided by the medical officers of schools, and the Health Department, to supplement this information, made goitre, for a time, a notifiable disease. In addition it was decided, in view of the modern belief that a deficiency of iodine intake is responsible for this malady, to investigate the iodine content of soils and vegetables. In this investigation Professor Heiatus, of the department of public health in the University of Otago, with whom were associated Mr C L Carter, lecturer on chemistry. Then reports is of great interest. The incidence of goitre was shown to be very low in regions underlain by igneous rocks yielding clayey soils rich in iodine, and high in regions where the soil is very deficient in iodine. "Any deficiency of iodine in the soil is reflected in the vegetables grown therein, and is the latter constitute our principal source of iodine, and no amount of safety or below it. In the former case the border-line of safety or below it. This demand may be a physiological one, such as menstruation or pregnancy, or it may be due to infection or to an unbalanced diet, but the end result is always the same—namely, thyroid enlargement." At the Medical congress of the New Zealand Branch of the British Association in February, 1924, a resolution was passed urging the Government to introduce the use of iodized salt into endemic areas. As a result the Health Department inserted in its Food and Drug Regulations a definition of iodized salt, but no salt conforming to this definition appeared on the market. In view of the report, however, the Health Department will take further steps to ensure the use of iodized salt in areas where deficiency in iodine has been shown to exist.

Medical research is also being undertaken on a number of other problems. Professor Heiatus and Dr Hector are conducting an investigation into the origin and mode of spread of infantile paralysis, the Government having put aside a sum of £2,000 for this purpose. A grant has also been made to Dr Renfrew White, orthopaedic specialist, Dunedin Hospital, to enable him to conduct an inquiry into rheumatoid arthritis and allied conditions. A commencement has been made also of an investigation of the cruet problem. It will receive increased impetus from the brilliant work of Gye and Barnard in this country.

These activities demonstrate how keenly alive is the Health Department to the imperative necessity of the high standard of health throughout New Zealand, with so well organized and active a department of health, with its divisions of public hygiene, infant welfare, school hygiene, Maori hygiene, dental hygiene, and food and drugs, there is every reason to believe that the ahead very high average health in New Zealand will be more than maintained.

Scotland.

EDINBURGH DIVISION IN RADIOLOGY

In connexion with the new pathological department, which is under construction in the Royal Infirmary of Edinburgh, the University of Edinburgh proposes to institute a diploma in radiology. It is expected that a portion of the new department will be ready for occupation on January 1st, 1926, and the remainder, consisting of the electrical and massage sections at a later date. The course in radiology is expected to include instruction upon the uses of radium rays, and ultra-violet radiations for which there will be a full equipment. The course in physics will be conducted by the professor of this subject in the university and a series of lectures upon radiology will be delivered by Dr. Woodburn Morrison, the head of the department and lecturer on radiology in the university. The intention is to give an essentially practical course, which will take up the whole day, during a period of approximately nine months. During the medical terms it is proposed to consist of six lecture demonstrations, which will be occasional short courses for undergraduates, which will from time to time to conduct brief courses specially concerned with the working of a ray apparatus, for practitioners who may be interested in this subject but who have not at their disposal sufficient time to take out the complete course for the diploma in radiology.

SCOTTISH ASYLUMS' PATHOLOGICAL SCHEME

The twenty-eighth annual report of the Board of the Scottish Asylums' Pathological Scheme (1924) has recently been issued. It states that arrangements were completed during the year with the authorities of the University of Edinburgh for the recognition of the superintendent of the laboratory as lecturer in neuropathology to the university. The board elected to the post of superintendent Dr. J. L. Reynolds, senior assistant to the professor of pathology at the Egyptian Government School of Medicine, Cairo. He took over his duties at the laboratory in the beginning of October, 1924. For several years past a grant from the Asylums' Board has been paid by the Medical Research Council to the laboratory for scientific research work. Intimation was received last year from the secretary of the Research Council that, in future, grants would only be awarded for special research work which had received the approval of the committee of the Research Council. A grant of £200 for the current year was made to the superintendent in respect of his researches into the path of infection of the lepto-meninges. The laboratory in Frederick Street, Edinburgh, which had been occupied by the late Dr. Ford Robertson, is being continued for the present till more suitable premises can be obtained, but it is hoped that it will be continued for the laboratory will eventually be found in the university buildings. Meantime the work is being done in a room of the pathological department at the Royal Infirmary, Edinburgh. The board had been pleased to note that, in response to an application which it had made, a Civil List pension of £100 a year had been awarded to the widow of the late Dr. W. Ford Robertson in recognition of his services to science and medicine. The revenue of the board for 1924 amounted to £1201 17s. 5d., of which £792 17s. 4d. was paid by twenty contributing institutions, and £25 is one quarter's salary from the university to the pathologist and lecturer. At the annual meeting of the board Dr. G. Douglas MacRae was unanimously appointed chairman of the board in succession to Dr. Skeen, whose term of office had expired. Dr. R. D. Campbell was appointed honorary secretary and treasurer.

WESTERN ASYLUMS' RESEARCH INSTITUTE

The fifteenth annual report of the work carried on at the Laboratory of the Scottish Western Asylums' Research Institute, Glasgow, has been issued by Dr. William Whitelaw. The opinion is expressed that, owing to the increase of cases of typhoid fever in asylums, this disease

[THE JOURNAL OF THE ROYAL SOCIETY OF MEDICINE]

will come to occupy the position held by diphtheria in asylum practice towards the end of last century. Attention is drawn to the need for the early recognition of cases of the disease and early isolation. Reference is made to the treatment of general paralysis of the insane by malaria inoculation, and to a later method which is under trial at present on some what the same principle. This consists in the development of protein shock, the aim is to cause the patient to develop rigour and a high temperature for some hours. Incoming results have already been obtained in the treatment of eight patients treated in this manner. The question of chronic infection from the alimentary canal as a cause of insanity is also being investigated.

Ireland.

THE ESTABLISHMENT OF A SEPARATE MEDICAL REGISTER FOR THE IRISH FREE STATE

The decision of the Irish Free State Government to establish a separate medical register for the Irish Free State to which we made reference last week continues to excite the very strong opposition of almost united medical profession and of a unanimous and influential body of the few medical members of the Dail had been decided for some time that the position was not satisfactory and that there had been a decided change of front in the attitude of the medical profession in the Executive Council of the Government. The decision of the Government to put up the best fight it can to bring about a change in the attitude of the Government. In this it will not only have the assistance of the daily press which generally supports the public, which believes that a serious error of policy has been committed by the Executive Council is the result of some mistaken idea in regard to the constitution of the Free State. It will be remembered that when the bill to confer registration in the Free State was being passed through the Dail, Mr. P. McCullagh, one of the representatives of the National University in the Dail and Minister for Commerce and Labour who had charge of the measure, in a speech in support of the bill said on July 17th, 1924:

We are only by a positive Act here continuing what we thought was continued by the Adaptation of Institutions Act. It may be said that there is some deterioration of status in accepting that but the other side of the question should also be considered that we get representation which is out of all proportion to our medical Council and that Council supervises the medical education not merely of the twenty-six or thirty-two counties, but of England, Scotland and Wales, so that we are getting definitely supervisory power really beyond our proper proportion.

There is reason to believe that the temporary bill would have been introduced in the Dail as a permanent measure if it were not for the opposition of the Irish leaders who opposed on economic grounds the continuance of the present arrangements for registration is encouraging the export of young medical men towards whose professional training the Free State contributed. The Irish have withdrawn his opposition when the Government agreed to pass the bill as a temporary measure. If the Government decided to make permanent the present temporary Act it is believed it could command a form to one majority in its favour. In the circumstances the change of attitude of the Executive Council of the Government is not easily understood.

Some professors of University College have stated that the hardships that would accrue to Irish graduates practising in England by the establishment of a separate Irish medical register have been unduly stressed, and that Australian and Canadian graduates may, without much difficulty, practise in England. In reply to this statement a prominent Irish member of the General Medical Council asks whether the Irish professors are fully cognizant of the provisions of the Medical Acts relating to the admission of medical graduates on the Colonial list of the General

register, and draws their attention to Sections 11, 14, and 17 in Part II of the Medical Act of 1886.

From these sections it will appear that there are two sides to the question of the application of the Colonial list to the Irish Free State. Let us for the benefit of these Galway professors go through these sections in their order. According to Section 11 which relates to the registration of a Colonial practitioner the applicant must prove to the satisfaction of the Registrar to the General Medical Council that the diploma or diplomas through which he wishes to be placed on the Colonial Register were granted to him at a time when he was not domiciled in the United Kingdom or in the course of a period of not less than five years during the whole of which he resided outside the United Kingdom. Section 14 which provides for a separate list of Colonial practitioners in the general Medical Register also enacts that the provisions of the Medical Act of 1886 relating to persons who are accused of penal cases of professional misconduct shall so far as they may be apply in the case of Colonial practitioners registered under the Medical Act of 1886. This means that these Colonial practitioners are liable to be tried by the General Medical Council for such offences. In Section 17 it is declared that His Majesty in Council shall define a colony to which the part of the Act (admission to Colonial List) shall apply. According to this the Privy Council (of England) will have to determine what shall be deemed to be a British possession to which this Act applies within the meaning of this part of the Medical Act. Until such Order in Council has been made in respect of any British possession then this part of the Act shall not be deemed to apply to any such possession. No more need be said beyond the fact that according to his interpretation the Irish State Government cannot obtain reciprocal arrangements with England as regards the Colonial Register unless—

- (1) They desire to be recognized as a British possession.
- (2) They wish to have their medical men tried by a foreign tribunal on which they have no representation.
- (3) They are content to wait until five years (one and a half years more) have passed since the setting up of the Irish State.

He would frankly advise the Executive Council of the Irish State—not to mention these Galway professors—to seek a legal opinion as to the bearing of these sections of the Medical Act on their proposals to establish a separate medical register and obtain reciprocity with the General Medical Council before they commit themselves to unforeseen and possibly disastrous pitfalls.

Dr. T. Hennessy, Irish Medical Secretary, made a statement last week to the *Irish Times*, in the course of which he said that it appeared that the only cause for the ruin of medical science in the Free State by the Executive Council was a mistaken notion of national dignity. So far as it was a gesture towards national independence it was ill chosen and futile. No doubt it would mean a self-contained and isolated medical profession in the Irish State consisting of some 1,500 independent and generally ill-treated medical practitioners for whom the present Government had refused to do anything to improve their condition. In a recent report, he said, the Government representative on the Committee of Inquiry devoted some columns to show that the dispensary doctors were too well paid when they received an average of £250 a year—less in many cases than their travelling expenses. He concluded his statement in the following terms:

As the result of the decision of the Executive Council doctors with Irish diplomas will have no better standing than quacks in those countries where hitherto they were with their colleagues on terms of professional equality. There are no new guards or old guards in the Irish medical profession although there is reason to believe that the graduates of our youngest university—the National University—will suffer not and that its medical school with its historic past will be only a shadow of its former self.

BELFAST MENTAL HOSPITAL

The ninety-fifth annual report of the Belfast Mental Hospital contains the reports of the committee of management of the medical superintendent (Dr. S. J. Graham), the memorandum of inspection of Colonel W. R. Dawson, Inspector of Lunatics and Principal Medical Officer of the Ministry of Home Affairs of Northern Ireland, the financial statements and thirty-two tables of various statistics of many kinds—for example, admissions, ages, forms of disease, deliriums and suicides. There are also several excellent photographs and a large bird's-eye view of the whole institution, which stands in some 500 acres of land in a beautiful suburb of the city. Attention is drawn to the constantly increasing need for more accommodation, four new buildings are already in course of erection. It would have been interesting to have had figures clearly showing whether this demand is due to past overcrowding of the wards and to increase of population of the district and not to increase of insanity. As no census was taken in the first year of the decade this is a difficult matter, but the views of the

medical superintendent would have been of interest. The necessity of an amendment of the lunacy laws is referred to, and here again the considered opinion and an outline of the hoped for changes would have been a useful guide to the profession in the province. At the end of last year there were 510 male and 531 female patients in the asylum, the admissions, discharges, and deaths differed little from those of the previous year. The treatment of general paralysis of the insane by the induction of malaria fever has been continued with satisfactory results, out of a total of 48 patients, 14 have been discharged, and 12 are marked as well improved. Emphasis is laid on the hereditary factor in the causation of insanity, mental stress, the critical periods, and syphilis come next in frequency in the records. Alcohol excess is given as a contributory cause in 6.8 per cent. The question arises whether the recent epidemics of encephalitis had any effect in the forms or numbers of insanity. It is very satisfactory to note that the number of patients to whom parole is granted is high, and that practically in no case is it abused, and also the freedom from suicide, homicide, mechanical restraint, and seclusion. A large amount of useful work was done by the patients. The inspector's report is uniformly favourable, and often laudatory. The suggestion may be made that many would like, in future reports, to have the professional part of the medical superintendent somewhat enlarged, annotated, and illustrated by his own personal views and framed so as to aid the profession in the endeavour to keep abreast of the study of a different and kaleidoscopic part of his work. Psychological medicine is increasing in importance and if the profession be not educated it will become a battle between the true specialists and the quacks, and the former will lose the aid of an educated body of opinion.

Correspondence.

SUCCESSFUL TREATMENT OF FIBROSITIS AT HARROGATE

SIR—Like many of my colleagues, I have hitherto been inclined to regard spa treatment more in the light of a diversion for the well-to-do than as an actual curative measure. Personal experience of Harrogate has quite eradicated this misconception, and I give the contents of your columns for a short account of my experiences at Harrogate.

For many years I have been subject to fibrositis in various forms and, about a month ago, while returning from a confinement in the "wee sm' boos," I was seized with severe disabling pain in the lumbar region. Acting on previous experience I at once took to bed, and applied hot fomentations, followed by strong iodine to the affected part. Massive doses of salicylates, saline aperients, dieting, etc., gave no relief, diathermy, ionization, radiant heat, etc., did not have much effect, so I decided to give Harrogate a trial, after two weeks of severe discomfort at home.

On arrival at Harrogate I at once sought advice from my old colleague Dr. R. A. Morris, who straightway gave me a general application of ultra-violet rays by means of the mercury vapour lamp—in passing I may mention that I had already tried the tungsten rays without appreciable benefit—and was surprised to find that I was able again to assume an erect posture and to walk home without severe pain. The following day I began to take the waters—sulphur at 8 a.m. and magnesium at 11 a.m. and 3 p.m.—and experienced no discomfort therefrom. At 3.30 p.m. I had the deservedly famous "Harrogate hot in bath," at a temperature of 300°.

I faithfully took the waters every day, and had hot and ultra-violet rays on alternate afternoons, with the pleasing result that I was able to play nine holes of golf, without apparent ill effect, within a week of arriving at Harrogate. After ten days' treatment I motored home in my open car, and have since experienced no harmful results.

I cannot speak too highly of the many advantages the Harrogate Corporation freely places at the disposal of members of our profession, and desire to recommend to my suffering colleagues the facilities which Harrogate offers gratuitously to them. Harrogate has numerous

comfortable hotels and hydropathics, first-class concerts may be enjoyed free by medical men three times daily and good orchestral music is played in various public places from 8 a.m. on. First-class facilities are provided for all kinds of sport, and medical people are allowed to play golf at Oakdale free of charge.

I think I ought to state, in conclusion that I have no financial interest whatsoever in Harrogate; my only desire is to express my gratitude for so much kindness and benefit received—I am, etc.,

Dudl. A. Whitby, Harrogate, Aug. 19th

INFORMATION

WRITINGS AIRIALS IN LIGHTNING STORMS

SIR—Dr. Jothagill of Harrogate has kindly drawn our attention to an item in your JOURNAL of August 15th (p. 294) under the heading of "Memoranda," dealing with the case of lightning striking an aerial and injuring a person standing close to the lead in wire of this aerial. The article states that apparently the form of protection against lightning risks by cutting an aerial is useless. Our opinion on this subject is that a wireless aerial properly erected and well earthed with a good cutting switch which is kept clean or by means of plug-in contacts, which the thundercloud will cause the potential stream between the thundercloud and the aerial to be lowered, due to discharge from the aerial, so that a lightning flash will not take place between the cloud and the points immediately in the vicinity. This is the principle of the lightning conductor.

However, it is possible, due to sudden changes in cloud formation during a thunderstorm, for the potential to rise so rapidly that even this protection will not lower the potential quickly enough to prevent a flash taking place and then, of course, a certain amount of damage may be done.

In the particular case quoted by your correspondent, had the earthed aerial not been there, there would seem every possibility of some other point on the house being struck, with results which would probably have done very considerably more damage and the person who was unfortunately slightly hurt might have been killed.

If the above contention is not correct then many structures such as church steeples, tall buildings, and high aeries, would be struck and partially demolished during a thunderstorm—I am, etc. (for the Maricomphone Co. Ltd.),

THE MORTALITY AND COMPLICATIONS OF DIPHTHERIA

SIR—With great diffidence I should like to draw attention to three points in connexion with diphtheria and to ask for the opinion of others. The three points are shortly (1) The persisting mortality from diphtheria, (2) the apparent increase of post-diphtherial paralysis of all limbs, and (3) albuminuria and nephritis as sequelae of diphtheria.

I have been in charge of a joint isolation hospital serving four urban and three rural districts for twenty-seven years, and have been much struck by the changes which seem to have accompanied the modern treatment of diphtheria.

In the first place no one will I think deny that the promise of twenty years ago, when antitoxin treatment was first adopted that diphtheria mortality would be greatly diminished has not been fulfilled. A glance at any of the weekly returns of the Registrar-General will make this clear. Take the quarter ending June 20th, 1925 and the figures for London and the great towns, and compare the mortality from diphtheria with that from scarlet fever. The weekly average of cases of scarlet was 867 with an average of 12.6 deaths. The weekly number of cases of diphtheria was 551 with 28.5 deaths. If the case mortality of diphtheria had equaled that of scarlet fever the weekly average of deaths would have been 7.6 compared with 12.6 instead of which it is 28.5—practically four times as great. Now did we not all hope and expect

when antitoxin treatment was introduced, that the result in the near future would be a marked diminution in the diphtheria death rate as compared, for instance, with scarlet fever? Certainly I so hoped. There is no question of the effect of antitoxin when used early. One's confidence in it continues to be justified weekly. What then is the reason for this continued rate of mortality? Is it that antitoxin is not used soon enough? Is it that too much is given? Or is it the result of sequelae?

2 I have been greatly struck by the apparent increase of post-diphtherial paralysis. In the pre-antitoxin days one used to note cases in which the palate and limbs were paralysed as showing rather an unusual complication. Perhaps two or three out of ten cases would show some degree of paralysis. My experience is that now practically every case shows some degree of paralysis of the fingers and that more serious forms of paralysis are correspondingly more frequent.

3 In the old days, although urine was tested daily for albumin in every case of scarlet fever, no such daily testing was considered necessary in the diphtheria ward and a small amount of albumin in the urine of a diphtheria patient was regarded as being associated only with the initial fever of a sharp case and rightly so as far as my recollection goes. In other words, one was not so much afraid of albuminuria in the diphtheria ward. Now I have learnt to dread the appearance of albumin in cases of diphtheria almost more than in scarlet fever. The sequence is now so often—first albuminuria and then that horrible sickness that seems to presage heart failure in diphtheria.

When I look back on the promise of the opening century with phthisis showing a steady annual decline, housing improvement promising all over the country and antitoxin discovered for diphtheria, I am conscious of these housing troubles worse than we have ever known them and the continued mortality from diphtheria. The great war for the third. It may be that one was young and hopeful then and now is old and disillusioned. I used to think in 1898 when isolation hospitals were provided practically in every district that I should live to see scarlet fever—hitherto stamped out. But as regard diphtheria I hope to hem the opinion of others and shall be glad to be proved in the wrong—I am, etc.,

August 19th

H. CAMERON KIDD,
M.O.H. from 1901 and North
Brom. Prov. Urban Districts

* In order to clear the ground it may be useful to quote the statements with regard to scarlet fever and diphtheria in the annual report of the Ministry of Health for 1924-25 recently issued, they refer to England and Wales. As to scarlet fever, the statement is "84,654 cases of scarlet fever were notified during 1924, as compared with 85,603 cases in 1923 and 108,242 cases in 1922. The mortality rate continued to decline, being only 10.5 deaths per 1,000 of notified cases as compared with 11.6 in 1923." As to diphtheria the statement is "The prevalence of this disease continued low, although notified in excess of the previous year, 41,980 cases being notified as compared with 40,009 in 1923. The mortality rate, however, fell to 60 deaths per 1,000 of notified cases, as compared with 68 per 1,000 in 1923."

THE ADDITIONAL VOLUNTARY HOSPITAL ACCOMMODATION REQUIRED

SIR—Whilst not desirous of belittling the two eulogies appearing in your last issue on the recent report of the Voluntary Hospitals Commission, it should be obvious to all that the opinions appearing over the signature of the chairman of the Hospitals Committee of the Association are only to be taken as his own opinions, that committee not as yet having had an opportunity to consider the report. There are several fundamental questions to be asked and replied to before the medical profession should decide to give the report its blessing. The Hospitals Committee and the Council will see to this, no doubt, and will consult the profession.

In the meanwhile it would be foolish for the medical profession to fail to recognize that here we have yet another instance which goes to prove that it lives in a changing world and that it will be greatly affected by new conditions which may be developed. For the State to subsidize anything cannot but result in the formation of a combine in which the State will be one of the partners, and, despite the emphatic statements of this school of thought which lingers at such a possibility, this partner will inevitably, sooner or later, be compelled by the force of public opinion and of those providing the money to take an active and direct concern in all things affecting the voluntary hospitals so subsidized.

The definition of this "direct concern" is fundamental. Having in view that the profession advocates one centralized local health authority, the domestic service under the National Insurance Acts, the various State clinics now in being, it is no longer possible to ignore the fact that the provision of an efficient hospital service is the last requirement, and that this is about to come to pass.

It would therefore seem desirable that the medical profession should take, as soon as may be, the long view and see that the menace of State bureaucratic organization and control, however insidiously developed, or however attractively hidden, does not by its stranglehold bring about the hushening of a free and liberal profession.

The whole profession—not only the staffs of hospitals as the report recommends—should see to it that it is consulted in this the latest scheme by which the voluntary hospitals are to be developed, and by the State—I am, etc.,

Hove Aug 22nd

E ROWLAND FOTHERGILL

WHAT IS AN EYE SPECIALIST?*

SIR,—Dr A F Feigus's letter (April 25th, p 804) on the subject of "What is an eye specialist?" contains material which is of considerable interest to the profession and of great importance to the public.

In the future there is no doubt but that an eye specialist will be a registered medical man who holds a special diploma or degree in ophthalmology, but at present any registered medical man may lay claim to such description. It would be impracticable for obvious reasons to demand of the present generation of eye specialists a special diploma or degree, yet the public should be protected as far as possible in the General Medical Council.

A post graduate appointment (resident or non resident) in a recognized ophthalmic (teaching) hospital or a general hospital with a recognized ophthalmic department or hospital ophthalmic practice of five years' duration could, in equity be insisted upon. Such a standard might be recommended by the British Medical Association in its advisory capacity to the Ministry of Health. I think that many men who are interested in ophthalmology are of the opinion that some such definition would be accepted by the administrative bodies.

Dr Feigus does not take a very favourable view of school eye testing. He points out merely the flaws in the system, but surely the medical inspection of school children in the aggregate should not be condemned on that account, neither do I think, because a few children who have no symptoms and +2 diopters of hypermetropia are missed, that the system of school eyesight testing should be condemned or that examination of every child under mydriatic is warranted. Personally I offer to examine under mydriatic all children whose vision is not 6/6, and also all children who have symptoms of eye strain.

Under this scheme the number of normal eyes examined under mydriatic is sufficient to render the work of the oculist extremely tedious. All myopes and astigmats are observed and such hypermetrops as are manifestly suffering from their hypermetropia. In order to observe the few children with low hypermetropia and no symptoms it would be necessary to submit the whole school population to examination under mydriatic and such a course is not, in my opinion, warranted. It would be best to let parents, if it would be a waste of the oculist's time, and it would also be an unwarrantable expense.

The ocular examination of school children is one of the

greatest benefits to be derived from medical inspection of school children. The system should be extended, but only where it can be carried out by medical men with the necessary training, and for this reason the necessity for a definition of "oculist" or "eye specialist" by the General Medical Council is apparent—I am, etc.,

REGISTRATION OF MIDWIVES AND NURSES IN SOUTH AUSTRALIA

SIR,—In the *BRITISH MEDICAL JOURNAL* of May 2nd (p 831) there appears a statement, reported to have been made by Dr B Dawson, relative to the control of midwives. The report states, *inter alia* "There was nothing in Australia corresponding to the Central Midwives Board and the country was in a similar condition to that obtaining in England twenty years ago, when a large number of entirely unsuitable and dangerous women were practising as monthly nurses."

As Registrar of the Nurses' and Midwives' Registration Board of South Australia, I would ask that this be corrected so far as this State is concerned. In South Australia there is a Nurses' Registration Act which includes the compulsory registration of general nurses and midwives, such registration being subject to a prescribed period of training having been undergone and prescribed examinations, set and conducted by examiners appointed by the Nurses' Registration Board, having been passed. This has been in operation here for the last three years and it is noted by latest advice from the Central Midwives Board that that body has recently adopted the same periods of training for midwives as have been in operation in South Australia for the last three years.

For your information I enclose copy of Regulations in operation in this State, relating to the training of midwives and nurses, also a copy of the Registration Act—I am, etc.,

Registrar

Adelaide June 18th

Obituary

J F GORDON DILL, M D, M R C P,
Consulting Physician Royal Sussex County Hospital Brighton

It is with great regret that we record the death of Dr John Frederick Gordon Dill at his residence in Hove on August 22nd, after a long illness borne with great fortitude and patience. He was 66 years of age, and was born in Brighton, being the son of Dr Richard Dill, who was in partnership with his uncle, Dr John Dill an old 1st Indian surgeon. Dr Gordon Dill was educated privately till he went to Cambridge. He completed his medical career at St George's Hospital, and spent some time in Paris. He graduated B A Camb, taking honours in natural science, in 1880, and M A in 1884. In the same year he took the degree of M B and also the diplomas of M R C S and L R C P. He proceeded M D in 1887, and took the M R C P in 1904. He started practice in Hove in 1884, and was soon appointed to the post of assistant physician to the Royal Sussex County Hospital later he became physician, and on his retirement from the active staff was elected consulting physician. He was a member of the British Medical Association; he had been chairman of the Brighton Division, and represented it on the Sussex Branch Council. He was also at the time of his death consulting physician to the Brighton, Hove, and Preston Dental Hospital, a Fellow and ex-member of the Council of the Royal Society of Medicine, honorary secretary of the British Provident Association for Hospital and Additional Services, and joint honorary treasurer of the Federation of Medical and Allied Services, he was also a member of the Brighton Insurance Committee and of the Brighton Panel Committee. He was recently appointed a vice president of the Fellowship of Medicine and Post-Graduate Medical Association. He had held the office of President of the Brighton and Sussex Medical-Chirurgical Society. He was surgeon major in the Hampshire Yeomanry, which he joined at

the time of the Boer war, and afterwards transferred to the Norfolk Yeomanry when the late King, Edward VII, raised the regiment. During the great war he served first with his regiment and later at the office of the A D M S for Sussex, for which services he was awarded the O B E. All those who had the privilege of working with him at the office of the A D M S remember with gratitude his kindly thought and consideration for them. He had of late years, recognizing the precarious position of the voluntary hospitals, interested himself in starting a scheme—the Sussex Provident Scheme—for the provision of hospital and additional medical services for those who were of the working class or were unable to afford the expenses of a serious illness, by means of the payment of a small insurance fee. Into this scheme he put his whole heart, and worked most energetically to make it a success. Starting with a few members in the first year, the scheme now numbers many thousands, and the result is due entirely to the energy and work of Dr Gordon Dill.

Dr Gordon Dill was well known to the practitioners of Brighton and Hove, his courteous and kindly disposition had endeared him to them all, and they recognized that in everything he did the interests of others were put before his own. There are many doctors in Brighton who could give examples of this great trait in his nature. He published many papers in the various medical journals, including "Some considerations upon the possibilities of future legislation in matters of public health" (presidential address), *Lancet*, 1891, "On pyrexial tachycardia and its relation to Graves's disease," *Proceedings of the Brighton and Sussex Medical-Chirurgical Society*, 1893, "Notes on some cases of skin diseases treated by thyroid extract" *ibid.*, 1894, "The plague of consumption" *Hospital*, 1895 "Pernicious anaemia treated by mill-sonning ferments" *Proceedings of the Royal Society of Medicine*, 1908, and others.

He married the daughter of Mr Simon Nicholson Martin of Hove, late of the Indian Civil Service, one of the defenders of Lucknow, where he served as a volunteer soldier. He had two sons—John Martin Dill, late of the 5th Lancers, and Richard Dill, late of the 1st Life Guards—both of whom are living. To his widow and his two sons our deepest sympathy is expressed in their great bereavement.

On the occasion of the death of a brother during the war, Dr Gordon Dill wrote the words and composed the music of a beautiful hymn, which was sung at his funeral on August 27th.

DONALD ACKLAND, L D S AND M R C S, L R C P, Bath

To the grief of all who knew him, Mr Donald Ackland died at Bath on August 17th at the age of 50. He was a son of Mr Robert Ackland of Exeter, brother of Mr J M Ackland of Exeter, of Mr W R Ackland of Clifton, and of the late Mr R C Ackland, dental surgeon to St Bartholomew's Hospital. Mr Donald Ackland was educated at Charing Cross Hospital and the Royal Dental Hospital, London. He obtained the diploma of L D S R C S Fng in 1897 and those of M R C S Fng and L R C P Lond in 1899. Shortly afterwards he began practice as a dental surgeon in Bath. His skill in his profession was quickly recognized, and he rapidly built up an extensive practice. He took an active but unobtrusive part in the medical life of the city. He was an original member of the Bath Clinical Society, as well as a member of the Bath Division of the British Medical Association. He was a regular attendant at the meetings of both and his contributions to their proceedings, both in the form of original papers and in participation in discussions, were greatly valued.

Mr WILFRID G. MILFORD, Acting President at the Annual Meeting at Bath, to whom we are indebted for most of these particulars writes "Quiet and somewhat reserved in manner, the unvarying kindness of his disposition endeared him to all who knew him, while his fine character rendered him universally esteemed and respected by his medical brethren. At the recent Annual Meeting of the Association in Bath he held the important post of

chairman of the Transport Subcommittee, and carried out the duties of that office with characteristic thoroughness and devotion. He organized personally all the arrangements for the various excursions in a most masterly manner. It was tragic irony indeed that he should have been struck down just when he had completed all the details of his scheme and should have been prevented from carrying out himself. How splendidly it worked and how greatly it contributed to the success of the meeting must always be remembered by all who attended. Mr Ackland's health had been indifferent for some years, and the fact that he never spared himself but always gave of his best, must have taxed further to weaken his constitution, but the sudden blow by which his career has been cut short in its prime has come a great shock to his many friends. The medical profession of Bath has sustained a great loss and one which will be long felt."

Mr Ackland leaves a widow for whom the deep sympathy will be felt in her great loss.

PIRCIVAL LANGDON LANGDON DOWN,

M B, B Ch Camb
Teddington Middlesex

We greatly regret to have to record the death on August 15th of Dr Percival Langdon Langdon Down at his residence at Teddington. He was a son of the late Dr Langdon Down, physician to the London Hospital and was born in 1858. He was at Harrow and Trinity College, Cambridge, and received his medical education at the London Hospital where he was house surgeon and house-physician. He graduated M B, B Ch Camb in 1893 and was also M A of that university. He was associated throughout his life with his brother, Dr R Langdon Down, in the direction of the well known institution for mentally defective children at Normansfield, Hampton Wick. He had long been a member of the British Medical Association, and at the time of his death was vice chairman of the South Middlesex Division. For over twenty years he had taken active part in the public work of the district. He became a member of the Teddington Urban District Council in 1905, and on six occasions between 1907 and 1924 was its chairman. In 1905, too, he became a member of the Thames Conservancy, and was chairman of the Lock Stiff Committee. He was also chairman of Richmond Bridge Commissioners and of the Thames Valley Councils Association since its formation in 1914. During the war he was chairman of the Local Control Committee. He found recreation in boating and was commodore of the Thames Sailing Club. He married in 1899 the second daughter of the late Mr James Bigwood of Wickenham, and leaves two daughters and a son. A memorial service was held at St Alban's Parish Church, Teddington, and the body was cremated at Woking.

We regret to record the death of Dr WILLIAM HERVEY PLAISTER on August 11th, at the age of 82, at his residence in Tottenham. Dr Plaister received his medical education in Bristol and Berlin, he obtained the diploma M R C S Fng in 1866 and the L S A in 1867. He commenced practice in Tottenham in 1868, and held the post of medical officer of the Tottenham and Edmonton General Dispensary until about two years ago, he was also district poor law medical officer for Tottenham. He had been a member of the British Medical Association for more than forty years. His son, Dr Geoffrey Plaister, who was killed in the war, had been previously in partnership with his father for ten years.

Dr JOHN DUFFY WINNE died on August 4th, at St Martin's, Guernsey, after a sudden illness lasting three days. Dr Winne received his medical education at Trinity College Dublin where he graduated M B, B Ch, I M in 1885, he obtained the diploma M R C S Fng in 1888, and the D P H (R C P S I) with honours in 1902. His appointments included house-surgeon to the Jessop Hospital for Women, Sheffield, resident to the Adelaide Hospital, Dublin, and medical officer of the Nottingham

Borough Fever Hospital Dr Wynne possessed considerable literary ability, and was for some time associated with the *BRITISH MEDICAL JOURNAL* as a reporter of Sections at the Annual Meetings. He contributed articles on tuberculosis in Ireland to the *JOURNAL* and other periodicals.

ALBERT JOHN OCHSNER, who died at Chicago on July 25th, was one of the leading surgeons in the United States. In 1900 he was appointed professor of clinical surgery in the University of Illinois, and held the chair until his death. In the same year he was elected chairman of the section of surgery of the American Medical Association. In 1910 he was president of the clinical congress of North America, in 1923 president of the American College of Surgeons, and in 1924 president of the American Surgical Association. He was an honorary Fellow of the Royal College of Surgeons in Ireland and of the Royal Microscopical Society. His numerous publications included a textbook of clinical surgery for practitioners and students (1905), a handbook on appendicitis (1906) and a treatise on surgical diagnosis and treatment (1918). He was the editor of the *Yearbook of Surgery* from 1917 to 1923.

Universities and Colleges.

UNIVERSITY OF DURHAM

In the list of those who received medical degrees on July 1st which was published in the *BRITISH MEDICAL JOURNAL* of July 11th (p. 94) it should have been indicated that Mr C C Ungley had obtained the M.B. B.S. with second class honours, he was also the recipient of the Philipson scholarship.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

Surgery—T K Clifford C D Cogswell V G Crowley S W Cuff
A L Evans W O H Evans T H Harrison A H Henson
J Herbert E P Hyde A P Osbourne W I Pierce F Reynolds
H A Sack G H Shanley N Schwartzman I Waynik
Midwifery—C D Cogswell W Hinds F P Hyde M V Roberts
Forness Munger—O Bastable E P Hyde L J Newman
M V Roberts I Waynik
Pharmacy—R F Ashkenasy A L Evans W Ier E H Rampling
M V Roberts C H Spencer

The diploma of the Society has been granted to Messrs A H Henson J Herbert W I Pierce A B Osbourne and I Waynik.

Medical News.

IN consequence of representations made during the debate in the House of Commons on the Diseases of Animals Act, 1925, the Minister of Agriculture and Fisheries has issued a new order (Tuberculosis Order of 1925 No. 2). It has been made after communication with the Ministry of Health and the Scottish Office, and applies to Great Britain. It provides that in any case in which a carcass slaughtered under the previous Order is intended to be used for human consumption, a copy of the notice of intended slaughter sent to the owner shall also be sent to the appropriate officer of the sanitary authority of the district, together with a statement of the address of the premises on which and the time at which it is intended to carry out the slaughter. The Order further provides that in any such case the carcass shall not be removed from the premises or be disposed of for human consumption without the consent in writing of the medical officer of health or other competent officer of the sanitary authority, or, in the case of Scotland, the meat inspector. The Minister of Health has sent copies of the Order to all sanitary authorities in England and Wales.

DURING the year ending March 31st, 1925 the Central Council for Infant and Child Welfare organized a day nursery at Wembley, in conjunction with the British Red Cross Society, and reorganized and extended its own travelling exhibition. A permanent exhibition is being established at Carnegie House, 117, Piccadilly, the headquarters of the council comprising model garments for infants and children, and the following sections: dental, clean milk diet riclets, tuberculosis and cripples. An arrangement has been made with the College of Nursing whereby its library has been placed at the disposal of infant welfare workers and students. Various courses of lectures have been delivered, and £450 has been given in grants to constituent societies of the council.

THE KING has promoted Sir William Maurice Abbot Anderson, VVO, physician to H.R.H. Princess Royal and household, to be a Commander of the Royal Victorian Order.

DR WALTER GRIPPER of Wallington, on the occasion of his retirement after forty years practice in the district, has been presented by his friends and patients with an illuminated address and a writing desk as a mark of their esteem and appreciation of his services.

THE KING has given directions for the appointment of Dr John Owen Shucore, Director of Medical and Sanitary Services, to be an official member of the Executive Council of the Panganyika Territory.

THE Indian Government has selected Lieut Colonel F P Mackie, director of the Bombay bacteriological laboratory, and Drs A Souza and B B Brahmachari, assistant directors of public health in the United Provinces and Bengal respectively, to take part in the tour in Japan this autumn of public health officers of the Far East. The tour is under the auspices of the League of Nations.

ON the occasion of the centenary of its foundation the firm of D Appleton and Co of New York has published a small book containing an essay entitled *Portrait of a Publisher* by Mr Grant Overton, and a chronological record showing how the firm began, how it was the publisher in America of the books of Charles Darwin and Herbert Spencer, and of Osler's *Practice of Medicine*, and how it also published books of lighter kind such as *Alice in Wonderland*, *David Harum* and *Uncle Remus* and many novels. The firm is perhaps best known to medical readers in this country by its encyclopedic works; it has published many of them, not a few in several editions.

MESSRS H K LEWIS AND Co will shortly issue a book on malignant disease of the testicle by H R Dew, and the second edition of *The Pathology of Tumours*, by Dr E H Kettle.

THE Transactions of the Eleventh Annual Conference of the National Association for the Prevention of Tuberculosis, which was held on July 6th and 7th, have now been published and may be obtained from the secretary at 20, Hanover Square, London, W1. On July 11th (p. 73) we gave an account of this conference, which considered in particular two subjects—tuberculosis in childhood and the sanatorium treatment. It is probable that many interested in these subjects will be glad to avail themselves of the opportunity of obtaining a full report of the speeches and discussions.

THE Rockefeller Foundation has decided to defray the expenses for ten years of a periodical entitled *International Biological Abstracts*, which will commence publication on January 1st, 1926. It has also presented 300,000 dollars to the Vaccine and Serum Institute of Copenhagen directed by Professor Madsen.

THE following have been nominated professors in Italian universities in dermatology and syphiligraphy, Ulder Capelli at Turin, Cosimo Lombardo at Pisa, and Alberto Seira at Cagliari in general pathology, Francesco Pentimalli at Cagliari and Alberto Varrasini at Sassari, in human anatomy Emerco Luna at Palermo, Nello Baccari at Catania and Giovanni Vitali at Cagliari, in histology and general embryology, Torni Inilio at Padua.

DR LINA STERN, formerly assistant to the professor of physiological chemistry in the University of Geneva, has been appointed to the chair of physiological chemistry in the University of Moscow.

THE *Archivos de gastroenterologia y nutricion*, the first issue of which appeared in May, is a quarterly journal devoted to gastrointestinal disease. It is published at Havana under the editorship of Professors Solano Ramos y Delgado and Leonardo Garcia Fox. The first issue contains original articles by Professor Ramos on the nervous system in digestion, by Dr C Flaudin on the treatment of amoebiasis by treparol by Professor Fox on the importance of diathermy, by Juan J Delgado on vitamins and nutrition, and by Dr Juan M Perez Boudet on the gastric symptoms of tuberculosis. These original articles are followed by abstracts from current literature and a bibliography.

THE Eleventh International Congress of Hydrology and Climatology will be held at Brussels from October 10th to 14th under the presidency of Professor Gilbert of Paris and Dr Terwinge of Brussels. The following subjects will be discussed: hydromineral and climatic treatment of cardiac vascular affections introduced by MM Cottet Mongeot and Piotot, hydromineral sulphur cure, introduced by MM Flamin, Liacre, and Lumorgue. The subscription is 50 francs for members of the congress and 25 francs for ladies accompanying them. Further information can be obtained from Dr Poirot Delpech, 3 Rue de la Planche Paris, VII.

AN Italian Society for the Scientific Study of Tuberculosis was founded at the Italian Antituberculosis Congress recently held at Naples.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W C 1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1 on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are *MUSEUM 9361 9362 9363*, and *9364* (internal exchange four lines).

The TELEGRAPHIC ADDRESSES are
EDITOR of the *British Medical Journal*, *Antology Western*,
London

FINANCIAL SECRETARY AND BUSINESS MANAGER
(Advertisements etc.) *Articulate Western* *London*

MEDICAL SECRETARY, *Medicera Western* *London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus Dublin* telephone 4737 Dublin) and of the Scottish Office 6 Darnsleigh Gardens Edinburgh (telegrams *Associate, Edinburgh* telephone 4361 Central).

QUERIES AND ANSWERS

ANATOMICAL NOMENCLATURE

DR A HARPISON WHITT (Cambridge) writes—In the review of Buchanan's *Anatomy* (*BRITISH MEDICAL JOURNAL* August 15th, 1925 p 296) the following statement occurs: "We are glad to see that the old nomenclature has been adopted in its entirety." I should like to know whether this voices the opinion of the majority of anatomists or whether the old nomenclature is likely to be retained in future in most textbooks.

* * We cannot say that the statement quoted voices the opinion of the majority of anatomists although we are informed that when the matter was considered at a meeting of the Anatomical Society of Great Britain and Ireland there was a very large majority in favour of retaining the old nomenclature. In consequence the University of London and the Royal Colleges of Physicians and Surgeons declared in its favour and adopted it at all their examinations. It would be hazardous to venture on a statement as to what will be the nomenclature of the future but we think it probable that a compromise will be reached with however the old nomenclature predominantly represented.

LETTERS, NOTES, ETC

SURGICAL EMPHYSEMA AFTER LABOUR

MR G W DANDO (Bexley) writes: The following case seems to be of interest owing to its comparative rarity. A primipara aged 28 after a prolonged labour which was ended by forceps delivery of a child weighing 9½ lb developed emphysema involving first the lower eyelids then the neck and upper part of the chest owing no doubt to a wound caused by staining. The left eyelid was very puffy before the forceps were applied. The condition caused her annoyance for some days. She had difficulty in opening her eyes in the mornings for a day or two and 'cracked' considerably but it cleared up completely in about ten days. The lungs are quite normal.

SUBNORMAL TEMPERATURE

P C D writes: In reply to my questions in the *BRITISH MEDICAL JOURNAL* of July 25th Dr S Vere Pearson asks (August 8th p 278) why one should trouble about a patient's subnormal temperature if he feels fit. This is a very good question. It is however far from disposing of the matter even if one discards the purely scientific consideration of subnormal temperature. The sense of well being is well known to be often very deceptive. For example people with quite advanced renal or arterial disease will often enjoy life so keenly as to be quite unaware of the dangers threatening them. If another example is needed one can point to puerperal sepsis where in some cases for a time the patient's sense of well being is perfect. Dr Pearson also gives it as his opinion that a temperature of 97.2° which I regard as subnormal is normal in cool weather in the state of rest. We are taught that the normal body temperature is about 98.5°. The questions that I originally propounded therefore remain unanswered interesting as they are—namely (1) Is a subnormal temperature regarding 98.5° as normal an indication of a pathological process and if so should it be regarded as an indication

tion for investigation and treatment (for example with thyroid extract)? (2) On the other hand can a subnormal temperature result from an inborn anomaly of the temperature regulating centres? Dr S Vere Pearson makes a very interesting reference to a book called *Doctor's Diary* wherein the opinion is expressed that people with slow pulses and low temperatures are more than ordinarily intelligent. The patient I have in mind would make an excellent example for the author—he is certainly more than ordinarily brainy.

MARINELLI'S CHILDHOOD

DR T H PIER (Loughborough) writes: When examining the refraction of a girl aged 8 at the school clinic I found +4.5 sph with 1 D cyl VV and prescribed +2.5 with a cylinder. With her glasses the child could or would see nothing. The father also brought a specimen of her writing. Without glasses it was quite good with glasses it was small and illegible. The father wrote to the headmistress that he had paid for the glasses and was bitterly disappointed. At a subsequent examination I found that even +0.25 lens had the same effect. I then tried the writing test. Without glasses writing was large and good with them it was small and illegible as before. I then convinced the lensless child she knew ledge and the small scribble persisted. This was proof even to the father that the child did not intend to wear glasses and would not acknowledge that she could see with them. The curious thing is that one so young should be so persistent in deception.

MISSES WHOOPING COUGH AND BRONCHOPNEUMONIA

DR SAMUEL SAMUEL (Leeds) writes: Dr Hugh Smith's note (August 15th p 316) is very interesting. Though I have not had an exact example like his in which whooping-cough has intervened. I have had several cases in which measles has been followed by bronchopneumonia and after resolution a fresh attack of measles has appeared. Bronchopneumonia in the fashion often interrupts a case of whooping-cough (as far as one can judge by the cessation of the spasmodic cough) and the whoop returns in full blast after the pneumonia has subsided. Dr Samuel thinks that the explanation is to be found in what takes place in a child when a second organism is superimposed upon the original one, the new organism asserts itself for a time and then the first organism re-asserts itself overcomes the new one and starts its life cycle over again.

TETANUS

IN use of a tetanus antiserum during the last war to a great extent mitigated one of its worst horrors but the serum was not always available and so search has been made to discover a suitable method of vaccination. A sporulating organism such as this offers almost insurmountable difficulties to the use of the bacillus as a vaccine owing to the high resistance of the spores and as research has had to be undertaken in other directions. Descombes (*C R Soc de Biologie* 1921 vol 2 p 239) also *BRITISH MEDICAL JOURNAL* 1st June August 9th 1924 para 165) has experimented with a tetanus antitoxin—the toxin deprived of its toxicity by heat and formaldehyde. Previous attempts have been made with analogous products—notably by Vallee and Bazy some years ago who used a mixture of the toxin with Crémé's solution. This however in addition to being not very satisfactory in operation rapidly deteriorated and soon lost its value. In the horse and man a good has been obtained by the injection of a serum on the discovery of a deep penetrating wound but there is still a considerable mortality in horses due to and so covered wounds. It is towards providing a vaccine for this animal that Descombes has directed his most recent researches (*Ann de l'Inst Pasteur* 1925 p 485). His experiments seem to show that the vaccination of the horse against tetanus is practicable and that injections of the antitoxin render the animal refractory to a very heavy experimental infection. The duration of the resulting active immunity has not been definitely established but it seems to be at least several months. The work is not yet finished and much has to be done before the antitoxin will be available for general use. If the ultimate results come up to expectations not only will a very considerable service have been rendered to one of man's best friends but it will open the way to very important consequences to man himself.

LAWSON LINT

IN the review of the book *Lawson Lint His Life and Work*, by Dr J Stewart McKay published about three years ago (*BRITISH MEDICAL JOURNAL* 1922 vol 1 p 1032) the revival of the gossip that lint was the natural son of Sir James Simpson was deprecated and dates were given which made it extremely improbable. The writer of the review has called our attention to an announcement of Mr T P O'Connor's reminiscences published in the *Sunday Times* of August 16th in the course of which Mr O'Connor states that Lawson Lint with whom he was on friendly terms volunteered the statement that the story was not true and that he came of perfectly respectable though not distinguished parents.

VACANCIES

NOTIFICATIONS of offices vacant in universities medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 28 29 32 and 33 of our advertisement columns and advertisements as to partnerships assistantships and locumtenencies at pages 30 and 31.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 104.

LONDON SATURDAY, SEPTEMBER 5TH, 1925

EDUCATIONAL NUMBER, SESSION 1925-26

THE CHOICE OF MEDICINE AS A CAREER

BY

CHARLES BUTTAR, M A, M D CANTAB

Why does a boy decide to become a doctor? From the opening addresses still delivered each year at some of the medical schools by eminent leaders of the profession, who have long since forgotten their own motives, the answer would appear to be that the boy is inspired solely by the lofty ideal of helping suffering humanity. But human action is rarely the result of a single motive. With few exceptions the sequence of motives in the selection of the profession of medicine is, probably, the need for making a living, the influence of environment, such as contact with relatives who are doctors or schoolfellows who intend to be, the glamour of the respect shown to the doctor, emulosity. The instruction now given in schools in the elements of such sciences as biology and physiology must increase the strength of the motive of curiosity. The compound of these ingredients, spiced in many cases with the idealism of youth, is the primum on which the profession of medicine is nourished.

Idealism is a very valuable spice, but it needs tempering with the milder condiment, humility. Moreover, it is sublimated from the emotions, and therefore needs the corrective of reason. There is a tendency among medical men in their public utterances to make too much of the great and noble profession, with its hard work and scanty reward. Any occupation may be great or noble, hard and ill paid. The ideal prison can be just as noble, just as hard-worked, and worse paid than the doctor. Idealism is quite possible in the lawyer, perhaps even in the stockbroker. I have never ceased to marvel at the greatness of soul of the ideal serjeant, his work would revolt me more than the gruesome-ness of dissecting or *post-mortem* rooms. It is well to leave to the public the estimation of the greatness and nobleness of our profession, to admonish students privately on the maintenance of a lofty aim in life, and to limit our utterances in public and in the press to practical questions which must be answered by every student and practitioner at some time in his career.

QUESTIONS FOR THE ASPIRANT

The first question that a would-be medical student should put to himself—he will not do it, but his parents or guardians might do it for him—should be "Is my standard of general culture sufficiently high?" To avoid trespassing on the domain of idealism, this question may be dismissed at once with the answer that the standard of culture can never be high enough, notwithstanding the examination in general education which the student is required to pass. The second question is "In what kind of medical practice do I intend to engage myself?" The choice lies between public and private practice, though the two overlap. Public practice is salaried, and may be military or civil. Military service—in the Navy, Army, or Air Force—has certain limitations in the matter of the age of retirement according to the rank attained, and in its needs only lessened incentive to hard work. But pay and pension are assured, so that one of the anxieties of private practice does not exist. Civil medical service has a later age of retirement, less assurance of pension, and in many cases less pay, but

greater independence, and consequently larger scope for advancement. As socialization of the community advances more and more appointments become open to doctors. But the pecuniary possibilities are never likely to equal those of private practice. It is desirable that the highest type of doctor should enter the public services since it is through these men that the mass of humanity is ruled. A service of cultured and intelligent men is less likely than a mediocre service to make the community uncomfortable with harassing restrictions, cast-iron rules, or futile and expensive experiments.

The majority of students will become private practitioners. Private practice may be either special or general. Special practice is rightly regarded as a higher grade than general practice, its practitioners should be doctors of high intellectual capacity. Unfortunately success in this branch of practice involves considerable expenditure for the purpose of "keeping up appearances", so that high intellectual capacity needs, for comfort, to be combined with private means. This need, however, prevents overcrowding of the higher grades of the profession. It was recently the fashion amongst some specialists to adopt a tone of mock humility in talking of the general practitioner, and to suggest thereby that the general practitioner was a person much superior to themselves. This was mere hypocrisy, and therefore unseemly. It is true that many men of great intellectual capacity become general practitioners, some prefer this practice, others cannot afford the special practice they would prefer. The will of these men is of the greatest value to the department of general practice, in that it sets a standard for the branch of medicine in which the majority of students ultimately become absorbed. In a temporary lull into idealism it may be suggested that the general practitioner should be one who is capable, not only of selecting the specialist suitable for a particular case, but also of criticizing, in the light of his knowledge of the patient and his surroundings, the opinion of the specialist, and of advising the patient whether he shall adopt the specialist's advice or not.

The student who is destined to become a general practitioner has many questions to ask himself at one stage or other of his career. Let him not think that the National Insurance Department of the Ministry of Health has settled his status by defining the duties which are within the competence of the ordinary general practitioner. A general practitioner must be prepared to be faced with any and every ailment and accident that the human being is liable to suffer. Hence rises the danger that he may regard himself as a universal specialist. He must ask himself "Am I capable of judging my own limitations?" Unless he is capable of doing so, his patients will suffer from ill-performed operations, from prolonged courses of useless vaccines manufactured on erroneous diagnosis, from regimes of sour milk to satisfy baseless hypotheses, or from expensive health resort treatments for non-existent disease. To avoid these catastrophes the student must be well trained in diagnosis in every branch of medical practice. It is far more important that a general practitioner should be able to recognize early an attack of glaucoma than that he

should be able to perform circumcision or an amputation operation for adenoids. Yet eye work used to be regarded at hospitals as a luxury while countless students tried to scrape out the contents of the nasopharynx. There are some branches of medical practice in which the general practitioner should, as a rule, outshine the consultant, such are the management of confinements and the feeding of infants. But even in these matters the important things are the power of diagnosis and the recognition of limitations, so that a case of congenital stenosis of the pylorus, for example, may be referred for appropriate treatment.

The next question the student should ask himself is "Have I the courage to be honest?" This is a very difficult question. In all ages the human being likes to have somebody or something to look up to and venerate, to whom or to which he may attribute the power he would like to possess himself. Most people venerate politicians, and think that they must be made of some superior clay. In the Middle Ages the priest was regarded as all wise, the lawyer has had his turn, and the poet, painter, and composer have never ceased to emphasize the superiority of their mental powers. But in the home the doctor has been supreme, and the assaults of quacks and faith-healers of all descriptions throughout the ages have failed to displace him. The doctor has to keep up a reputation for wisdom, will he, by being honest, give the position away? When pressed with questions by importunate patients, a doctor should be strong enough to say, "I do not know."

Supplemental to this question of courage to be honest is the question "Am I truthful?" The probability is that the more truthful a doctor is the better for the advancement of mankind, for science, as Huxley said, has learnt that the foundation of morality is to have done, once and for all, with lying. Nevertheless, this question also is difficult, and perhaps, as another scientist used to say, not yet ripe for dogmatic statement. In cancer, is the sheep, hungry for life and looking up to the doctor, to be fed with lies or annihilated by the truth? And how many of these we try to spare would be annihilated by the truth? And shall the inquiring wife of a repentant, but gonorrhoea stricken, husband be lulled to peace, or stimulated to suspicion? For meeting such questions the student may well ask himself, "Am I the soul of discretion?"

INCREMENTS OF SUCCESS

If a young man, well educated, decides to enter the medical profession as a general practitioner, is willing to try to recognize his limitations, is honest, discreet, and, as far as possible, truthful, he may wish to consider some of the factors of success. No man can possess all these factors, nor is any man so insipid as to be able to please every patient. But the more of these factors a doctor possesses, the more patients he will please.

It is not possible to define personality, nor is it possible to describe or to cultivate the type that impresses. To assume the appearance of wisdom when no wisdom exists may not be strictly honest, but there is no doubt that an appearance of wisdom conferred by nature may be a valuable asset. The attraction of personality may be increased by attention to various details. Thus it is within the capacity of most men to cultivate some measure of sympathy and charm of manner. With an effort many can make themselves alert and businesslike. Attention to personal appearance, and to the ordering of the house from which the practice is conducted, is important. The medical man has too often tried to live up to his reputation of being unbusinesslike. He may be unpunctual, or careless about noting and keeping appointments. And apart from the effect on his practice, a lack of business capacity may have disastrous effects on the doctor and on his family.

It is sometimes said that the appearance of prosperity is often a better asset than the possession of knowledge. The public can recognize a smart motor car, but not the power of diagnosis. Hence a doctor may embark on expenses which his income cannot meet, and if he dies early his wife and family are abandoned to the charity of his friends and colleagues. From his earliest days the student should be impressed with the necessity when in practice of keeping his expenses within the limit of his means, and with making provision for contingencies. The cost of this provision should be a first charge on his income, and such provision should be made at the earliest opportunity—if possible, during student days. All medical men should have insured their lives, all should have insured against sickness and accident, all should have joined a defence society, all should subscribe to the medical charities, and all should be members of the British Medical Association.

PUBLIC HEALTH SOME GENERAL CONSIDERATIONS.

BY

HENRY KENWOOD, O.M.G., M.B., D.P.H.,

EMERITUS PROFESSOR OF HYGIENE IN THE UNIVERSITY OF LONDON.

THE importance of developing the teaching of the preventive aspect of medicine in the ordinary curriculum of the medical student is now fully recognized. Sir George Newman in 1919¹ made an eloquent appeal to this end, and to the Educational Number for 1923 he contributed an article on the "permeation" of the medical curriculum by preventive medicine. He observed that the chief glory of the present age—which he called "the Golden Age"—of medicine has been the advance of prevention, and pointed out that "it is now generally acknowledged that the ultimate purpose of the science and art of medicine is not to cure the individual patient only, but to seek out the laws or principles which govern health or ill health for the human family." He appealed to the medical student to give attention to the subject. "There are," he said, "not less than a score of Acts of Parliament which impose public preventive duties upon the medical practitioner, and 'it is required of him that he shall take an essential part in the vast national and international machinery now in being for the conquest of disease.'" The General Medical Council by the date of the article in these columns from which I have quoted had revised the medical curriculum and had recommended that the preventive aspect of medicine "should be a pervading influence all through the curriculum, affecting every subject in it, so that the student naturally and almost unconsciously adopts in his daily practice of medicine the attitude and spirit of prevention." When this comes about

the medical practitioner will the better realize the responsibility attaching to his unique position for the application of effective measures of preventive medicine, and a better foundation than exists at present will be laid for the curriculum for the Diploma in Public Health.

The fact must be recognized that those who undertake the work of a medical officer to a public health authority devote themselves to a service which, to the very large majority, does not offer a prospect of pecuniary reward equal to that which attaches to successful private practice, but a medical official performs a valuable work in congenial circumstances, given that tact, consideration, and conscientiousness which command popularity and success, and the public health worker enjoys a greater freedom than the busy practitioner—a fact which has led many of the latter to join the ranks of the former.

A medical man who desires to enter the public health service as a career must, as a first step, obtain a Diploma in Public Health, and details of the way in which it may be obtained are given at page 447. The Regulations of the General Medical Council demand that the granting of such a diploma shall be proof of the "possession of a distinctly high proficiency, scientific and practical, in all the branches of study which concern the public health." Most of the universities and licensing corporations now grant such diplomas to candidates who pass the examinations provided by them, some universities grant degrees in the subject, but these are generally available only to their own graduates.

¹ An Outline of the Principles of Preventive Medicine 1919

In 1910-11 the Board of Studies of Hygiene of the University of London, of which I was chairman, prepared a report for the consideration of the Senate upon the need of a university centre in London for post-graduate instruction and research in hygiene and public health, and upon the desirability that all such teaching in London should be given in one centre, made worthy of the capital of the Empire. Ten years afterwards the Post-graduate Medical Committee, appointed under the chairmanship of the Earl of Athlone by Dr Addison, then Minister of Health, made a similar recommendation. Thanks to the munificent gift of the Rockefeller Foundation the scheme of a London School of Hygiene and Tropical Medicine is soon to be practically realized. When the building is ready, in about two years as is hoped, and the school is prepared to undertake post-graduate teaching in public health in all its branches, there is every probability that all such teaching in London will be concentrated within its walls. The new institute is to be a recognized school of the University of London, and the existing London School of Tropical Medicine, which has already done such good work, will be an integral part of the new school, which has the advantage of being under the able direction of Dr Andrew Balfour, C B, C M G, D P H. Not only will full emersion of study be provided for the Diplomats in Public Health and in Tropical Medicine and Hygiene, but special opportunities will be given to post-graduate students to receive instruction and conduct research in these subjects. "Refreshed courses" of instruction will also be provided. It is intended that a great graphic museum of hygiene shall be a notable part of the provision made. This will be of real value, and its section of tropical medicine and hygiene will certainly provide a source of interest and instruction to visitors from the dominions, colonies, and dependencies. The part in practical education which such a museum is capable of playing has never been fully exploited in this country.

Under the new regulations for a Diploma in Public Health the huge majority of students take Part I of the examination at the end of their first five or six months of special work and anyone may commence work with this object as soon as a registrable qualification in medicine, surgery, and midwifery has been obtained. The candidate will then have disposed of the more exacting part of the examination and be left with only six months of subsequent work before taking Part II of the examination, after the prescribed period of two years has elapsed since he obtained his registrable qualification. Formerly it was easy to obtain some kind of remunerative work during the period of training but under the new regulations the student is so fully employed that this is hardly possible. Where this is essential, however, it can be done by spreading the D P H work over the period of two years.

To the prospective medical officer of health the training and experience in administrative work is of first importance. It must be as comprehensive as possible, so as to include every variety of "setting." No one medical officer of health can provide this wide experience nor demonstrate every variety of public health provision well organized and completely equipped, and so it is desirable that special visits and demonstrations should be arranged by the training centre and that these should be recognized as counting in the 180 hours of work with a medical officer of health. Above all the student training with a medical officer of health should be given an opportunity of seeing something of both urban and rural conditions, and when he is being instructed in the subject of industrial hygiene, school hygiene, and port hygiene, he should see for himself the conditions obtaining in factories and workshops, schools, and ships.

A wise post-graduate student will set himself to learn much more than he is taught, and he will lose no opportunity of doing and seeing all that he can. He will find, for instance, that his knowledge of the "setting" of public health work will be more usefully obtained from his efforts to become thoroughly familiar with the circumstances and conditions of life among the poorer section of the community than from a textbook on sociology—although the latter can always be consulted with advantage.

In conclusion it may be said that the mere possession of a Diploma in Public Health is seldom sufficient to secure an

appointment. It is necessary in addition to build up a record of experience in one or more branches of public health work, by acting as an assistant to a medical officer of health, or by obtaining clinical experience in eye, ear, and throat work, or by assisting in the work of a maternity and child welfare centre, a tuberculosis dispensary, a sanatorium, a venereal diseases treatment centre, a fever hospital, or in several of these ways. One who, after obtaining his registrable qualifications, has made up his mind to embark upon public health work, would be well advised to devote twelve months to gaining some special experience in the matters above indicated. He would then have a good prospect of securing an appointment. It need hardly be added that if his taste lies in the work of a medical officer of health, a school medical officer, a tuberculosis medical officer, a maternity and child welfare medical officer, or a venereal diseases medical officer, he should concentrate upon the special experience, clinical and otherwise, which relates to the kind of office he desires, a course embracing as many of these experiences as possible will help him to the administrative appointment of a medical officer of health.

The Profession of Medicine.

INTRODUCTION

For long past it has been our custom to publish a special Educational Number of the *BRITISH MEDICAL JOURNAL* at this time of year, shortly before the opening of the winter session at the medical schools. The remarks that follow, on the profession of medicine, are addressed more particularly to intending students and their parents. While it would be out of place to discuss medical politics here, the occasion may be taken to touch on a few current matters affecting professional study and practice. Our object in doing so is to put certain considerations before those who think of devoting themselves to medicine, and thus help them to judge of their fitness for the profession and of the prospects it holds out, for there is no walk of life in which a special vocation is more necessary, and few about which so many misconceptions linger in the public mind.

The Educational Number is largely a guide to the steps that must be taken in order to become a legally qualified practitioner. With the passage of years the form and contents of this issue have undergone more or less change, but its primary object remains unaltered. It contains also certain sections intended for younger members of the profession who may be in doubt as to the path in medicine they should choose as a career, and a section on the existing opportunities for post-graduate medical study in Great Britain. The particulars given under these two main heads are founded for the most part on official information, and are arranged along the customary lines. We publish also in this issue two introductory articles—the one by Dr Charles Buttai, a general practitioner of large experience, on the motives which may lead to the choice of medicine as a profession, and the other by Professor Henry Kenwood, in which he briefly sets out some general considerations on the choice of the Public Health Services as a career. This should be read in conjunction with the article giving further particulars on page 445.

Apart from these and other special articles, the prospective student will find in subsequent pages an account of the course of education required of him, the places where this training can be obtained, and the universities and other licensing bodies which test the knowledge gained and issue degrees or diplomas entitling successful candidates to become registered medical practitioners. Here we draw attention to the need, which increases with the advance of scientific medicine, for a thorough grounding in the fundamentals of science. As Sir Ernest Rutherford said five years ago to the Section of Medical Education at

the Cambridge Annual Meeting of the British Medical Association "In order to maintain and raise the standard of the profession, the medical teaching must be based on a sound basis of scientific principle. Without that, the energy and enthusiasm of medical teachers is largely wasted."

PORTALS OF THE PROFESSION

Perusal of the articles in this issue will give the idea that there is an almost bewildering number and variety of portals through which admission may be obtained to the *Medical Register*.¹ Nevertheless, although there is no single State examination in medicine in this country, the medical courses of the various universities and schools in Great Britain and Ireland run on parallel lines, and the obligatory curriculum is much the same in all. Within these broad lines, however, there are many differences between the requirements of the individual teaching and examining bodies. The choice should therefore be made early, so that a definite plan may be followed throughout the years of study. To prevent a false step at the outset the student and his advisers should try to obtain a clear idea of the object to be aimed at, of the relative advantages of taking one or other of the degrees or diplomas open to him, and of the comparative difficulties they present.

All who wish to enter the medical profession must comply with certain conditions. These are prescribed by the General Medical Council, which is a statutory body established under the Medical Acts, a statement of its requirements is given at page 410. Many changes have lately been made in the medical curriculum, and this section should be studied with care. Every medical student, after passing examinations in the subjects of general education and in the preliminary sciences, must take a course of training at a recognized medical school, covering at least a period of five years, but usually extended to six years or more. The examination of candidates as to their fitness to practise medicine, surgery, and obstetrics is left to the licensing bodies, which are of two kinds—the universities, and certain corporations in England, Scotland, and Ireland. One of the functions of the General Medical Council is to make sure that the tests at each stage do not fall below a certain standard, and that the students examined have undergone prescribed courses of instruction at recognized institutions. Successful candidates at such examinations eventually receive from the body holding them either degrees, in the case of a university, or diplomas or licences in the case of a corporation; these qualifications entitle them to claim insertion of their names in the *Medical Register* kept by the General Medical Council. Holders of diplomas and licences once made up the great majority of all medical men, especially in England and Wales. But universities have greatly multiplied, and many practitioners are now graduates that a student of ordinary ability will be well advised to aim at a medical degree, though it may be desirable to take also a diploma or licence.

COST OF MEDICAL EDUCATION

The question, What does a medical training cost? cannot be answered in a single precise statement, because the outlay varies within wide limits. Besides differences in the charges made by medical schools for instruction there are differences in examination fees as well as in the fees for certificates of qualification, and those who aspire to the higher degrees and diplomas must expect to pay more for the additional courses and tests and certificates. Again, not all students, however industrious, pass examinations with equal facility, and every setback due to failure in the examination room or to illness means added expense. Since professional education must in any case continue for

five years at least (a period exceeded by the vast majority), and since the cost of living in different parts of the country varies much, while personal expenditure varies still more, it can only be said in a general way that anyone who thinks of entering the profession should reckon on an outlay—first and last—of at least £1,500. On the other hand, the number of scholarships and prizes now offered is larger than in the past, in the Scottish universities bursaries are numerous, and the Carnegie Trust (whose regulations are summarized at page 421) gives financial assistance to many Scottish students. The main thing to bear in mind is that, as compared with other professions, the period of training in medicine is long, and for most students costly. There is also to be remembered the time of waiting after qualification when income is apt to lag behind expenditure.

THE NUMBERS OF MEDICAL STUDENTS

One effect of the war and of after-war circumstances was a great increase in the number of medical students, both men and women, but especially women. The following brief survey of the position should be read in conjunction with the note on page 409 on the numbers of registered practitioners. In the thirteen years before the war the annual entry of medical students in Great Britain and Ireland averaged about 1,400, during the war period, although many students left to serve with the forces, the whole number actually studying in the schools was growing steadily larger. In 1914 the entries rose to 1,600, and in 1915 to 1,918, in 1916 they fell to 1,875, in 1917 they rose again to 2,150, in 1918 to 2,253, and in the following year, when demobilization was in active progress, as many as 3,420 new students were registered. After 1919 the number of entries rapidly fell. In 1920 there were 2,531 registrations of new students, in 1921 there were 1,808, and in 1922 there were 1,833.

In 1923 the number dropped to 545, and the reasons for the fall were discussed by Sir Donald MacAlister in his presidential addresses to the General Medical Council. In his address last May he recalled that, speaking in 1924, he had expressed the view that the sudden decline was more apparent than real, and had attributed it to the recent introduction of a pre-registration test in elementary physics and chemistry. "This test," he continued, "many students would not pass, and so could not register, until the end of their first term, at least, after leaving the secondary schools. The explanation would seem to be sound, for in 1924 the registrations were nearly doubled, reaching 1,043 by the end of the year. As the working of the new regulation is better understood in the schools, and as the general and scientific education of intending medical students is brought up to the higher standard now required, there is little doubt that the number of qualified entrants on the medical curriculum will approach the pre-war figure of 1,300 or 1,400, a number sufficient to supply the needs of the country for qualified practitioners." In his address in May, 1924, he had said that the period of strain created by the war on the teaching resources of the medical schools and colleges had practically come to an end, and expressed the hope that "in the comparative calm which now prevails the teaching institutions would have leisure to introduce the improvements in the medical curriculum which, with their assistance, the Council had laid down as necessary or desirable."

The recent fall in students' registration is to be welcomed for another reason. Excessive entries of students lead to overstocking of the profession. In 1922, 1923, and 1924, the numbers of new practitioners registered greatly exceeded the figure indicated by the President of the General Medical Council in the passage quoted above. In 1924 the number of registrations, which had been 2,482 in 1923, rose still further and attained the large total of 2,796.

¹ The *Medical Register* is the official statutory list of qualified medical practitioners kept by the General Medical Council.

These recent large increases have brought the total number of names in the *Medical Register* up to 49,958 at the end of 1924, and the ratio of qualified medical practitioners to population is now greater than at any previous time. The new regulations, which came into force at the beginning of 1923, should do something to keep the entries of students—and as a consequence, the numbers of the profession—within manageable bounds.

CHOICE OF A CAREER IN MEDICINE

The student, having passed all his tests and placed his name on the *Medical Register*, becomes a member of the profession and assumes the privileges and responsibilities that go with legal qualification. But the final examination, though a great event, is only the opening of a door into a wider field of training and experience. Education must continue throughout his career: a good doctor remains always a student. As an introduction to practice nothing is so useful to the newly qualified man or woman as a year or more spent in junior hospital appointments, and all who can afford the time should look upon the holding of such posts as a most valuable investment. Next comes the choice of a career in the larger world of medicine. Many paths are now open—for example, general practice, Government service at home or abroad, and special work in public health and mental disorder, in scientific research, or in one of the many modern subdivisions of medicine and surgery. Most of these careers are discussed in some detail in the later sections of this number, but a few words may be said here about general practice and the work of a consultant or specialist. A good deal of information on these and other cognate matters will be found in the *Handbook for Recently Qualified Medical Practitioners*, published by the British Medical Association.¹

GENERAL PRACTICE

General practice is still the goal of the great majority of all medical students. The life is onerous and exacting. It has been said with much truth that of all professional men the general practitioner is the worst paid and the hardest worked. Nevertheless, general practice has its compensations, and, for one reason or another, it appeals to many of the very best students. Thus it comes about that this country continues to produce the finest body of general practitioners in the world.

This career is usually entered upon in one of three ways. The newcomer may take a house and wait for patients to seek his services, he may purchase the goodwill of a practice rendered vacant by retirement or death, or—perhaps best of all—he may become a partner in an established practice. A well managed multiple partnership has obvious advantages over single-handed practice, for instance, it allows each partner leisure for recreation and for keeping up with the progress of medical art and science. Success in the work of a private practitioner demands a great deal of knowledge other than that gained at the medical schools, and consequently a man is more likely to be accepted as a partner, or to do well on his own account, if he has already some experience of family practice as an assistant or deputy. A large proportion of general practitioners, therefore, begin their work as assistants.

An all-round knowledge of practical medicine, surgery, and obstetrics should, if possible, be supplemented by skill in some particular branch of practice. Moreover (as already indicated) the value to a general practitioner of having held one or more resident hospital posts is incalculable. In after-life (we quote the words of a great surgeon and teacher) one can generally pick out those who have been thus trained, as they gain a confidence and reliance and experience which they cannot easily obtain elsewhere.

Before leaving this subject it ought to be added that the strain of busy general practice is so heavy and often so continuous that only those of sound physique can hope to last the course.

CONSULTANTS AND SPECIALISTS

For those who aim at becoming consultants or specialists success will depend in the long run not only upon mental gifts and capacity for hard work, but (as is true of practitioners of all branches) on the possession of those qualities which inspire confidence both in patients and in colleagues. In practice, personal tact and character are as important as scientific equipment. Moreover, since the consultant or the specialist can scarcely hope at first to pay his way by consulting work or by the exercise of his specialty, he must either have the means to support himself for an uncertain period or be prepared by teaching or in other ways to defray expenses. A successful physician, surgeon, or specialist is made, not born, and the process of making himself is not remunerative.

The question of additional degrees and diplomas is of special moment to those whose ideas turn in this direction, if only because these are important factors in securing election to the visiting staff of a hospital. Beyond the qualifications, such as Bachelor or Licentiate, which admit to the *Medical Register*, most of the licensing bodies bestow higher titles, such as Doctor, Master, or Fellow, after further tests. For the career of a consulting physician the M.D. degree of a university is usually necessary, and also the Membership of one of the three Royal Colleges of Physicians, according to the part of the British Isles in which practice is contemplated. In the same way, the Fellowship of one of the three Royal Colleges of Surgeons should be sought by those proposing to devote themselves to surgery. There are also diplomas in a growing number of special branches of work, such as public health, tropical medicine, ophthalmology, radiology, and psychological medicine, which are superfluous for most practitioners, but either useful or indispensable for the medical man or woman who wishes to specialize in these subjects. Information about the several diplomas will be found elsewhere in this issue. For all consultants and specialists ample occasions for exchanging ideas and information with their fellow workers are most necessary. Such opportunities are provided by the various medical societies, by the scientific sections of the British Medical Association's Annual Meetings, and by the medical journals, both general and special.

FINANCIAL AND SOCIAL CONSIDERATIONS

It has never been easy to assess the attractions of medicine as a means of livelihood, and at the present moment this would perhaps be more difficult than ever. On the financial aspect of our profession two or three general observations only need be made. Medicine is not to be regarded as a path to fortune, and anyone who enters it with the sole idea of making money has mistaken his calling. The competent practitioner can always make a living, but the main reward of the medical life is the knowledge of good work well done. Whatever the branch of medical work chosen, there are few doctors who become what a business man would consider even moderately rich by the practice of their profession.

But if medical practice, from the financial point of view, offers to the majority little more than a means of livelihood, in its social and intellectual aspects the prospect is brighter. The culture which once belonged to the physician alone, entitling him to his place among members of the learned professions, has spread, and is spreading further, into all ranks of the practitioners of medicine. The great improvement in the education, general as well as technical, of the practitioner has added much to his influence in public

¹ *Handbook for Recently Qualified Medical Practitioners*. British Medical Association, Tavistock Square, W.C.1. 2. 6d. J.L.

life, and has been a large factor in raising his social status during the sixty-seven years that have passed since the General Medical Council was constituted under the Medical Act of 1858. A family doctor of the kind that is well styled "the backbone of the profession" occupies an excellent position among his neighbours, and is the friend and confidant as well as the medical advisor of many of his patients.

PRIVATE PRACTICE THE OUTLOOK

The prospects held out by the various public medical services are indicated in later sections. Here may be noted very briefly some circumstances of to-day that have a bearing on private practice. In the first place, efforts are being made to bring professional training more into line with the growth and differentiation of medical science, and so to raise the level of medical practice, it was with this in view that the student's curriculum was lately reconstituted. Next, the fundamental importance of the work done by the general practitioner is better understood, and it is more fully recognized that an efficient medical service for the community must be based upon the individual skill and devotion of the family medical attendant, working in close touch with the aims and methods of preventive medicine. The private practitioners of to-day are taking a wider view of their duties towards the environment and the habits of their patients. On the other hand, increasing contact with public duties makes new demands on the practitioner. The multiplication of official requirements and tiresome administrative details has a tendency to cramp his independence of action, and there are those who see in the "officialization of medicine" the gradual undermining of professional freedom.

The National Insurance system, now more than thirteen years old, has already had a profound influence upon the private practitioner and his work, so much so that it needs some little effort to recall clearly the conditions of industrial practice before the year 1913, both as affecting the medical profession and the large section of the community which became insured under the Act of 1911. The Insurance Medical Service now comprises nearly 14,000 practitioners, some doing much work among insured persons, others little. If the freedom of family practice and the robust individualism of the private practitioner have been restricted by the Insurance Acts and Regulations, there is a general belief that the panel system has provided a better service than existed under the old "club" arrangements, though it is by no means as complete or as effective as it might be made. Whether the remuneration is adequate to the services required may well be doubted, but it is easier now for a doctor to make an assured income out of attendance on working class patients.

The full effect of the insurance scheme upon the medical profession as a whole, and upon the private practitioner as an individual, is as difficult to gauge as its effect upon the public health. Some of its most objectionable features have been removed through the efforts of the Insurance Acts Committee of the British Medical Association, which is the central executive of the Local Medical and Panel Committees of the country, and represents, with conspicuous success, the interests of insurance practitioners in all negotiations with the Government. A Royal Commission is now sitting to inquire into the existing scheme, and to report what, if any, changes, extensions, or developments should be made in its scope, and in the administrative, financial, and medical arrangements set up under it. The scheme may therefore be considered as still in the experimental stage, and the future of private medical practice as still rather obscure.

PROFESSIONAL ORGANIZATION

The strong sense of *esprit de corps*, which adds so greatly to the value and happiness of undergraduate medical study,

is equally an advantage to the qualified practitioner. In these days no doctor, whatever his position or the nature of his work, can safely stand aside from his fellow medical men and women must therefore band themselves together for the common protection of their profession and themselves. Experience shows that individuals and isolated bodies of medical practitioners are always handicapped when they attempt to defend their own interests unsupported by their fellows against organized bodies. This applies, whether the organized bodies are Government departments, local authorities or bodies of workmen. While the individual doctor is quite capable of dealing with the individual patient, he requires an organization at his back when he is dealing with other organizations. The first step after qualification should be to become an active member of the British Medical Association. A young practitioner will find in the meetings of the local Division of the Association, and in the Annual Meetings held in large medical centres, many opportunities, not only of keeping abreast with the progress of medicine but also of friendly intercourse with colleagues. Another thing that no new graduate should fail to do is to join one of the professional societies which undertake individual legal defence of their members.

The British Medical Association was founded in 1832 to promote the medical sciences and to maintain the honour and interests of the profession. It is the great general forum of the profession, and it is the one organization which acts for the profession as a whole in times of stress. A brief note on the objects and constitution of the Association, and the advantages offered to members, will be found at page 459. The record of ninety-three years' work shows that professional organization, directed with wisdom and imagination, can successfully combine service for its members with service for the public. Greater work remains to be done in each direction, and we look confidently to the rising generation of doctors to take their share.

THE NEW LRA IN MEDICAL EDUCATION

A full account of the resolutions and recommendations of the General Medical Council which have applied since the beginning of 1923 is given in the present issue of the *JOURNAL*. Here we propose to indicate some of the salient features of the scheme, both of study and of examination.

The Revised Curriculum

The minimum age for registration as a medical student has been increased from 16 years to 17 years. Formally, the length of the medical curriculum is not added to, practically it is, by transferring to preliminary study and examination the subjects of elementary physics and chemistry in their purely scientific aspects. In the applications to the professional courses—as in biophysics, biochemistry, and pharmacological chemistry—appropriate instruction is to continue throughout the curriculum, and is to be tested by examination, so that the student shall no longer be able to put behind him as passed and done with the knowledge which he acquired as a preliminary. If he has had no facilities at a secondary school or otherwise for obtaining what is necessary for the preliminary examination in these subjects, then he can come for it to the university or college, but study there will not count for the medical curriculum.

In biology it is understood that comparatively few secondary schools are equipped for elementary tuition, but the Council has suggested an ingenious arrangement for utilizing the work of such schools as are qualified for the purpose. The examination will not be "pre-curriculum," but the instruction may be so, and a licensing body can allow students who so desire to sit for the examination immediately after matriculation. Here again, however, the applications of biology to medicine, surgery, and midwifery will continue to receive attention throughout the courses.

The Council attaches great importance to the reservation of sufficient time for the later subjects of study, free from all worries about passing the examinations of the earlier parts. To that end it recommends what is practically a block system. A minimum of three years should be available not merely after the courses of anatomy and physiology have been taken, but after the professional examinations have been passed. The value of this proposal is

Examination Reform

Another notable feature is that in assessing marks in the actual examinations account may be taken of "duly attested records of the work done by the candidate throughout his course of study" in the subject. This is in effort to meet the long felt difficulty that a man's mental ability or the want of it, counts far too much in his being passed or rejected. The difficulty is real, but the remedy is not easy, and the Council is wise in the cautious approach it makes towards a solution. Where, as in the colleges a student will only by chance come before his own teacher as in examination, absolute impartiality in the attested records will be necessary. A teacher must not play for popularity with students by too easy certification of diligence or success in class. On the other hand, at the universities, where the teacher is always one of the examiners, no personal like or dislike of a student must influence the report of the internal to the external examiner. The class records should of course, be available, but the scheme will put a serious ethical obligation on all concerned, and the Council will doubtless watch its operation with keen and critical interest.

Besides the resolutions of the General Medical Council in regard to professional education and examination (see pages 410-412) a series of additional resolutions was adopted on May 26th, 1922, as follows:

- That throughout the whole period of study the attention of the student should be directed by his teachers to the importance of the preventive aspects of Medicine.
- That each Licensing Body should make adequate arrangements for the effective correlation of the subjects of study throughout its curriculum.
- That the teaching of Anatomy and Physiology should include as a regular part of the courses the demonstration on the living human body of structure and function.
- That the curriculum should be so arranged that a minimum period of three years shall in every case be available for study after the completion by the student of the Professional Examinations in Anatomy and Physiology.
- That the curriculum should be so framed as to afford sufficient opportunities for the study during the last three years of the course of Physics, Chemistry, Biology, Anatomy, and Physiology in their practical applications to Medicine, Surgery and Midwifery, and that the student's knowledge of these applications should be subject to test in the Final Examination.
- That before the student is admitted to his clinical appointments he should have received practical instruction in clinical methods and in the recognition and interpretation of physical signs.
- That instruction should be given in the courses of Forensic Medicine and Public Health or otherwise on the duties which devolve upon practitioners in their relation to the State and on the generally recognized rules of medical ethics. Attention should be called to all notices on these subjects issued by the General Medical Council.

Training in Preventive Medicine

The first of these resolutions should be borne in mind by every teacher throughout the whole curriculum and not merely in the clinical subjects. As indicated in a questionnaire issued by the Council in 1918 all the various subjects—physics, chemistry, biology, physiology, anatomy and, of course, pathology, bacteriology, and therapeutics—also—afford opportunities from the very beginning for instilling into the mind of the student the necessity for his keeping constantly in view in all the advice and treatment he may give throughout his professional life, the primary importance of promoting the general health of those who entrust themselves to his care, and of preventing trivial ailments from developing into

definite disease. In his presidential address to the Council in 1918 Sir Donald MacAlister pointed out that if "the efficient practice of their profession" by doctors was "to be judged by new civic standards, and to be carried out under new conditions," the student would have to be trained accordingly. The era of that training began formally in 1923. Though no details are given in resolution (a), and though it may require some change of orientation by teachers who have hitherto given no special heed to the bearings of their subject on the maintenance of health and the prevention of disease, yet they will doubtless join heartily in what will indeed be an epoch-making advance in medical education in this country. Its reflex and reward will surely be found as time passes in a diminution of sickness and prolongation of life, in the raising of the present standards of physical health and national welfare.

New Rules for the D.P.H.

It is important to note the bearing that this development of the teaching of disease prevention to all students of medicine has upon the stringent rules which came into force for new candidates at the beginning of 1924 for the obtaining of Diplomas in Public Health (see page 447). It is expressed that the stiffening of the requirements will discourage those who intend to go into ordinary medical practice from taking the additional qualification which would specially fit them for co-operation with the health officer of their district. The reply is twofold. Henceforward all new practitioners will have received tuition qualifying them generally for such co-operation, and in addition they are already being systematically educated in "the duties which devolve upon practitioners in their relationship to the State." The balance, therefore, seems clearly on the right side as to the ordinary practitioner, and there will unquestionably be advantages in strengthening the education of those who aspire to a life spent in the public health service.

THE NUMBERS OF THE MEDICAL PROFESSION

A REVIEW OF FORTY-NINE YEARS
 SINCE the year 1876 the General Medical Council has kept an analytical record of the number of names entered in, added to, or removed from the *Medical Register* in each twelve months. The *Medical Register* has been published annually since the Council was constituted under the first Medical Act of 1858, but before 1876 no such data as these were ascertained or preserved.

In order to gain a general view of the numerical strength of the medical profession during the past forty-nine years we have extracted from the tables and set down in parallel columns the total number of names in the *Medical Register* on December 31st of each year, and the numbers added annually by registration between 1876 and 1924.

Numerical State of the Medical Register		
Year	Names added in Year	Total No. on Dec. 31
1876	1 009	22 713
1877	910	22 811
1878	996	22 600
1879	996	22 516
1880	1 123	22 936
1881	1 053	23 275
1882	1 171	23 601
1883	1 304	24 517
1884	1 338	25 321
1885	1 377	25 998
1886	1 431	26 452
1887	1 531	27 216
1888	1 184	27 939
1889	1 305	28 348
1890	1 265	29 163
1891	1 513	29 555
1892	1 345	30 590
1893	1 513	31 614
1894	1 579	32 637
1895	1 426	33 601
1896	1 446	34 478
1897	1 335	34 642
1898	1 230	35 057
1899	1 210	35 636
1900	1 351	36 355
1901	1 345	37 355
1902	1 345	38 355
1903	1 345	39 355
1904	1 345	40 355
1905	1 345	41 355
1906	1 345	42 355
1907	1 345	43 355
1908	1 345	44 355
1909	1 345	45 355
1910	1 345	46 355
1911	1 345	47 355
1912	1 345	48 355
1913	1 345	49 355
1914	1 345	50 355
1915	1 345	51 355
1916	1 345	52 355
1917	1 345	53 355
1918	1 345	54 355
1919	1 345	55 355
1920	1 345	56 355
1921	1 345	57 355
1922	1 345	58 355
1923	1 345	59 355
1924	1 345	60 355

The following table indicates the rising proportion of registered medical practitioners to population during the

3 A candidate remitted in any subject of a Professional Examination should, before he is readmitted to examination, be required to produce satisfactory evidence that he has, during the interval of remission, pursued the study of the subject in which he was rejected. Candidates who obtain less than 30 per cent of the marks in any subject should be remitted for a longer period than three months.

4 In all the Professional Examinations sufficient time should be assigned to practical work, in order to test the thoroughness of the candidate's knowledge and to encourage practical methods of study.

The requirements of the preliminary examination in general education being satisfied, it is then necessary to pass an examina-

5 Candidates in all their examination work should be carefully supervised.

6 Two examiners should always participate in the oral examination of a candidate, except in subordinate parts of practical examinations.

7 In all written examinations the questions in each subject should be submitted for the approval of all the examiners in that subject.

8 In all written examinations an average of at least half an hour should be allowed for a candidate to answer each question.

9 It is desirable that examiners, and in particular those for the Final Examination in Medicine, Surgery, and Midwifery, should be appointed or re-elected for at least three consecutive years.

10 Whatever may be the system of marking, the percentage for a pass in each subject should not be less than 50.

11 In the regulations for the several examinations it should be provided that examiners, in assessing marks, be empowered to take into account the duly attested records of the work done by the candidate throughout his course of study in the subject of the examination.

12 The Final Examination in Medicine, Surgery, and Midwifery, with the exception of the Clinical and Practical Examination in Midwifery and Gynecology, must not be passed before the close of the fifth academic year of medical study.

13 The three portions of the Final Examination in Medicine, Surgery, and Midwifery should not be further subdivided into sections which may be entered for or passed separately.

14 Compensation in respect of marks as between the three different portions of the Final or Qualifying Examination—namely Medicine, Surgery, and Midwifery—is contrary to the intention of the Medical Act (1886).

15 The Final Examination should include clinical and practical examinations in Midwifery and Gynecology.

16 The clinical examination in Medicine, Surgery, and Midwifery should be held in properly equipped hospitals or examination halls well provided with suitable patients.

17 In the examinations in clinical medicine at least one hour and in clinical surgery at least half an hour, should be allowed to the candidate for the examination of, and report on, his principal case.

18 In Medicine, in Surgery, and in Midwifery no candidate should be allowed to pass who fails to obtain 50 per cent. of the aggregate marks assigned to the whole examination, or who fails to obtain 50 per cent. of the marks assigned to the clinical examination, or who fails to obtain 40 per cent. of the aggregate of the marks assigned to the written and oral examination. In Midwifery, where a clinical examination is not held, the duly attested records of the work done by the candidate in clinical midwifery must be presented to the examiners for assessment in the Final Examination, and no candidate should be allowed to pass who fails to obtain 50 per cent. of the aggregate marks assigned to Clinical and Practical Midwifery and Gynecology.

19 The Final Examination should include the examination of secretions, the testing of urine, clinical microscopy, and prescription writing, and there should always be an oral examination in Medicine, Surgery, and Midwifery, which should include an examination on pathological specimens.

20 At the Final Examination each candidate should be submitted to a practical and oral examination in Pathology (macroscopic and microscopic), unless this has been included in a Professional Examination preceding the Final Examination.

21 Whatever be the method of entry for the Final Examination all candidates should be required to complete the three portions of the Final Examination within a period of nineteen months.

The English Universities.

There are eleven universities in England and Wales, and some account of each of them follows. They all have now fully developed medical faculties. Until recently the only exception was the University of Wales, whose constituent colleges are those of Aberystwyth, Bangor, Cardiff, and Swansea. This university grants degrees, and has laid down a six years' curriculum for candidates for the MB and BCh degrees, and it now provides, at the Welsh National School of Medicine at Cardiff (see page 419), instruction in all the subjects of the medical curriculum.

UNIVERSITY OF OXFORD

The professional degrees conferred by this university are those of Bachelor of Medicine (B.M.), Bachelor of Surgery (B.Ch.), Doctor of Medicine (D.M.), and Master of Surgery (M.Ch.). It also grants a Diploma in Public Health and

a Diploma in Ophthalmology. On receiving the B.M. the candidate is entitled to registration by the General Medical Council. In favourable circumstances this degree and the B.Ch. may be obtained in six or seven years from matriculation. Before receiving either, the candidate must have taken a degree in arts (B.A.), for which three years' residence within the university is necessary. This, however, does not necessarily mean deferment of professional study for that period, for the subjects chosen for the arts course may be the same as those in which examinations would in any case have to be passed for the medical degree.

In accordance with a statute which came into force on October 7th, 1920, women may be matriculated and admitted to degrees in the university. The statute is retrospective under certain conditions. Before matriculation a woman must have been admitted as a member of one of the five societies of women students (Lady Margaret Hall, Somerville College, St. Hugh's College, St. Hilda's Hall, or the Society of Oxford Home Students). Women members of the university are admitted to all degrees, except the LL.D., under the same conditions as those laid down for men in regard to examinations, courses of study, and fees, and under corresponding conditions as to residence at the university. Among the university diplomas open to women are those in anthropology, ophthalmology, and public health.

A candidate may obtain the B.A. degree in either of the following ways of which the former constitutes the normal course for medical students:

(a) By passing Responsions (or one of the examinations which are accepted as equivalent) the Scripture examination (one of the preliminary examinations in the Natural Science School, or the Honour School of Mathematics in the first public examination), and one of the final honours examinations—the final Honour School of Natural Science (Physiology) is that usually taken.

(b) By passing Responsions (or one of the examinations which are accepted as equivalent) Moderations a Scripture examination or in the event of a candidate objecting an examination on some substituted book, and the final Public School in three subjects two of which may be the same as two of the preliminary examination in natural science.

Responsions and the preliminary examinations in Natural Science may be passed before a candidate is a member of the university, Moderations and Scripture can be passed in or after the second term, the final pass school may be taken any time after Moderations, a final honours school may be taken at the end of the third or fourth academic year—that is, within nine or twelve terms respectively, the preliminary examinations of the Natural Science School may be taken as soon as Responsions has been passed or exemption obtained.

PROFESSIONAL DEGREES

To obtain the B.M., B.Ch. degrees the candidate must first pass in four of the subjects of the Preliminary Examination of the Natural Science School—namely, physics, chemistry, zoology, and botany.

He then has two further examinations to pass—the First B.M. and the Second B.M. These take place twice a year, the first on the Thursday, the second on the Wednesday, of the eighth week of Michaelmas and Trinity terms. Every candidate at the First B.M. is examined in human anatomy, in physiology, and in organic chemistry, but is excused from physiology if he has obtained a first or second class in the Honour School of Physiology, and from organic chemistry if he has satisfied the examiners in Part I of the Honour School of Chemistry. Once he has passed this examination he can, on production of certain certificates, be examined as soon as he pleases* in pathology, forensic medicine and hygiene, materia medica, and pharmacology (subjects of the second examination), but cannot present himself for the remaining subjects—medicine, surgery, and midwifery—until the eighteenth term from the day of his matriculation, and not until a period of at least thirty-three months has elapsed from the date of his passing the first examination, and he must pass in all the three subjects at one and the same time.

* The four subjects of the medical preliminary examinations are four of the subjects in the natural science preliminary, and can be commenced directly after passing Responsions.

Membership is constituted by matriculation and by becoming either a member of a College or a Hall or a non-collegiate student.

Before admission to the second B.M. examination the student must produce certificates of instruction from a medical school recognized by the university, of having acted as clinical clerk and dresser, each for six months, and as post-mortem clerk for three months, of attendance on labours, of instruction in infectious and mental diseases and ophthalmology, and of proficiency in vaccination and the administration of anaesthetics.¹ He must also produce certificates of attendance in laboratory courses in pathology, bacteriology, and pharmacology, either in Oxford or in a recognized medical school.

D.M. AND M.Ch. DEGREES

A Bachelor of Medicine who wishes to proceed to the D.M. must have entered his thirtieth term and must present a dissertation for approval by the appointed examiners on a subject previously approved by the Regius Professor of Medicine. If a candidate for the M.Ch. he must have entered his twenty-first term and must pass an examination, which is held in June.

Examinations for the Diploma in Public Health are held in Trinity and Michaelmas terms, that for the Diploma in Ophthalmology is held annually, commencing on the third Monday in July. For the Diploma in Ophthalmology attendance on a twelve months' course of clinical ophthalmology in hospitals or institutions recognized for the purpose by the Board of the Faculty of Medicine, and on a course of instruction in Oxford lasting two months, is obligatory. Candidates must have their names on the *Medical Register* of the United Kingdom, unless, being Bachelors or Doctors of Medicine of universities outside the United Kingdom, they have obtained special permission from the Board of the Faculty of Medicine.

TRAINING

The several colleges provide their undergraduate members with tutors for all examinations up to the B.A. degree. In addition, the university provides certain courses of instruction including lectures, demonstrations, and practical work, which cover all the subjects of the Preliminary Examination and First B.M. and those of the Final Examination.

SCHOLARSHIPS

Most colleges grant scholarships open to intending medical students of £80 a year, tenable for four years in natural science, chemistry, physics and biology. Exhibitions of varying value are also awarded in these subjects. At two colleges (University and Pembroke) there are medical entrance scholarships of £100 a year. Particulars can be obtained on application to the college tutors. Scholarships for women are also offered by the various women's colleges from the principals of whom details of the examinations may be obtained. A Padeliffe Travelling Fellowship of £300 a year, tenable for two years, is conferred annually; candidates must have taken the B.M. degree. A Philip Walker Studentship in Pathology of £200 a year, tenable for two years, is awarded biennially for the encouragement of research in pathology; it also carries the Rolleston Memorial Prize and the Padeliffe Prize (£50) for research in natural science (including pathology) and the three Theodore William Scholarships in Anatomy, Physiology and Pathology of the value of £50 each, tenable for two years. A Padeliffe Scholarship in Pharmacology of £50 for one year, open to the University, is awarded annually by the Master and Fellows of University College. A Butney Leo King's College Hospital Scholarship of £20 is awarded annually.

FEES

An annual fee of £4 10s. is paid to the university for the first four years, being reduced to £1 when the B.A. has been taken. For the degree the fees are: the B.A. £7 10s., the B.M. and B.Ch. £14, the D.M. £25, the M.Ch. £12. College fees, varying in amount, are paid for the first four years of membership and in taking degrees. Tuition fees vary from £21 to £30. The minimum annual cost of living during the three university terms may be regarded as not less than £180 or for women not less than £110.

For further information application may be made to Dr. I. W. Anley Waller, Dean of the School of Medicine, University of Oxford.

UNIVERSITY OF CAMBRIDGE

THE professional degrees given by this university are those of Bachelor of Medicine (M.B.) and Bachelor of Surgery (B.Chir.), each of which entitles the possessor to admission to the *Register* by the General Medical Council, and the higher degrees of Doctor of Medicine and Master of Surgery. It also grants Diplomas in Tropical Medicine, in Public Health, in Hygiene, in Psychological Medicine, and in Medical Radiology and Electrolgy to medical practitioners, not necessarily graduates of the university. In formation regarding these diplomas will be found in later sections under the headings Tropical Medicine, Psychological Medicine, Public Health, and Radiology. A candidate for the M.B., B.Chir. degrees need not possess a degree in arts, it is sufficient if he has passed the Previous examination or some other examination accepted by the university as its equivalent. Most students, however, are advised to take the B.A. degree, preferably by obtaining honours in the Natural Sciences Tripos at the end of the third year. Under the new regulations the attainment of a sufficient standard in chemistry or in physiology in this Tripos will secure exemption from the corresponding tests in the First and Second M.B. examinations. Women students, members of Girton or Newnham College, are now admitted to the M.B. examinations.

PROFESSIONAL EXAMINATIONS

To obtain the M.B. degree the candidate must pass three examinations, those who are finally successful may receive the B.Chir. degree (which is a complete registrable qualification) without further examination.

First M.B.—This comprises (1) general and inorganic chemistry, (2) mechanics, (3) physics, (4) elementary biology. The parts may be taken together or separately. In either case the candidate before admission to examination must have satisfied the requirements in respect of the Previous examination and paid the matriculation fee. Certain exemptions from the First M.B. examination are allowed, the regulations may be obtained from the Registrar. The complete examination is held twice a year—in October and June. An additional examination, in Parts 2 and 4, is held in December.

Second M.B.—This examination comprises Part I, organic chemistry, Part II, human anatomy and physiology, Part III, elementary pharmacology, including pharmaceutical chemistry and the elements of general pathology. No student is admitted to the first part of the second examination until he has passed the first part of the first examination. No student is admitted to the second part of the second examination until he has passed all parts of the first examination. No student shall be admitted to the third part of the second examination until he has passed the first and second parts of the second examination. No one may enter Part III unless he has passed Parts I and II. The candidate must be signed up in all three subjects and have dissected for one academic year. The examinations for Parts I and II are held in December and June, that for Part III in October and April.

Third M.B.—This is divided into two parts, to neither of which is the candidate admitted until he has passed the examinations previously mentioned. A candidate for the first part which deals with the principles and practice of surgery (including special pathology) and midwifery and diseases peculiar to women, must have completed five years of medical study and be signed up in these subjects and have completed two years and a half of hospital practice. Before admission to the second part the candidate must have completed five years of medical study and be duly signed up in all subjects and have completed three years of hospital practice. He must also possess certificates showing that he has fulfilled all the recommendations as well as the requirements of the General Medical Council. The examination is in the principles and practice of physics (including diseases of children, mental diseases, and medical jurisprudence), pathology (including hygiene and preventive medicine) and pharmacology (including therapeutics and toxicology). The Third M.B. examinations are held twice a year—in June and December.

¹ For the certificates that will be required for the new Regulations of the General Medical Council, Clarendon Press Oxford, 1925 edition.

The examination in Michaelmas Term is at present suspended.

Act for the M B—Before receiving his M B degree a candidate who has been successful at the final M B examination has to write a thesis. This he reads in public on an assigned day, and is then questioned concerning it and other subjects of medicine by the Regius Professor of Physic. If approved at this test he is then certified as having "kept the Act" satisfactorily, and in due course receives his degree. Medical degrees may be taken in absence by those living abroad, the candidate sending to the Regius Professor of Physic a dissertation, which is laid before the Degree Committee.

THE HIGHER DEGREES

The M D degree may be taken by a Bachelor of Medicine of three years' standing after writing a thesis approved by the M D Degree Committee, and keeping a further Act, at which he reads his thesis and is examined thereon. Previously to the Act being kept a topic taken from the general subject of his thesis (whether it be physiology, pathology, pharmacology, practice of medicine, State medicine, or the history of medicine) is submitted to the candidate, on which he is required to write an extempore essay.

The M Chir degree may be granted to a candidate who has qualified for the B Chir at least two years previously, he is then examined in pathology, surgery, surgical anatomy, and surgical operations. The tests are partly in writing, partly oral, and partly practical. They include the writing of an extempore essay.

FEES

In addition to college fees, tutorial fees and the expense of living the following examination fees are payable: First M B, £5 5s; Second M B, £5 5s; Third M B, £10 10s. For schedules referring to the examinations lists of schools recognized by the university and other information application should be made to the University Registry, Cambridge.

UNIVERSITY OF LONDON

UNDER the regulations of the University of London the degrees obtainable in the Faculty of Medicine are those of Bachelor of Medicine and Surgery, Master of Surgery in two branches, and Doctor of Medicine in six different branches. The university has its own matriculation examination, and this is of so peculiar a kind that candidates should obtain and carefully study the booklets relating to it. The matriculation examination is open to any person, of either sex, who has attained the age of 16. It is held in January, June, and September, and lasts four days, the first two take place both in London and in certain provincial centres, the September examination is held in London only.

In no circumstances is a degree granted to anyone in less than three years after the date at which he passed the Matriculation Examination or obtained registration in some other way, and, unless they are already registered medical practitioners of a certain age and standing, all medical students must pass not less than five and a half years in professional study subsequent to matriculation, of which the last three years must be spent at a school of advanced medical studies.

PROFESSIONAL EXAMINATIONS

M B, B S—There are three examinations, the last two being subdivided. They are held twice a year.

The First Examination (held in July and December) covers inorganic chemistry, general biology, and physics, there being two papers, a practical test, and a possible oral test in each subject. The names of successful candidates are placed in alphabetical order, with a note as to any subject in which a candidate has distinguished himself or herself.

The Second Examination is held in March and July. Part I cannot be passed within six months of the passing of the First Examination. It covers organic and applied chemistry, the candidate's knowledge being tested as in the earlier examination. It is a pass examination, but a mark of distinction may be won. Candidates for Part II must have passed the First Examination at least eighteen months previously, besides having completed Part I of the Second Examination. The subjects are anatomy, physiology, and

pharmacology, the tests being written, oral, and practical. Candidates who fail in one subject may sit for re-examination in that subject alone if the examiners think fit.

No candidate is admitted to the Third M B, B S Examination within three academic years from the date of his completing the Second Examination. The subjects are medicine (including therapeutics and mental diseases), pathology, forensic medicine and hygiene, surgery, and midwifery and diseases of women. They may be divided into two groups, one comprising medicine, pathology, forensic medicine, and hygiene, and the other surgery and midwifery and diseases of women. Either group may be taken first at the option of the candidate, or the groups may be taken together. Only candidates who have a competent knowledge of all the subjects comprising a group are passed. There is no separate examination held for honours, but the names of successful candidates are divided into an honours list and a pass list, and a university medal may be awarded the candidate who has most distinguished himself in the whole examination.

THE HIGHER DEGREES

M D—An examination for the M D is held twice yearly—in December and July. Every candidate must have passed the examination for the M B, B S, unless he became M B before May, 1904. He may present himself for examination in any one of the following branches: (1) medicine, (2) pathology, (3) mental diseases and psychology, (4) midwifery and diseases of women, (5) State medicine, (6) tropical medicine, and, if he wishes, may pass also in another branch at a subsequent examination.

The period that must elapse between acquiring the M B and sitting for the M D in any branch varies between one and two years, according to the nature of the candidate's previous work, and in all cases evidence must be afforded of special study of the subject chosen, both written and practical examinations must be passed, though exemptions can be obtained from the former in exceptional circumstances. In each branch the scheme of examination is the same: two papers on its special subject, a paper on an allied subject—for example, medicine in the case of branch (4), pathology in branch (1)—an essay on one of two suggested topics connected with the special subject, and a clinical or other practical test. In any branch of the M D Examination a gold medal of the value of £20 may be awarded.

M S—The regulations with regard to the Mastership in Surgery are of a corresponding kind, but there are only two branches in which it may be obtained—General Surgery and Dental Surgery.

FEES

The examination fees have been raised from pound to guineas for all examinations held after September 1st 1918: for Matriculation 2 guineas for each entry. First Examination 5 guineas for each entry to the whole examination. For re-examination in one subject the fee is 2 guineas. Second Examination Part I 2 guineas for the first and each subsequent entry. Second Examination Part II 8 guineas for each entry to the whole examination. For re-examination in one subject the fee is 4 guineas. M B, B S Examination 10 guineas for each entry to the whole examination. M D and M S Examinations 20 guineas and 10 guineas on re-examination.

Inquiries should be addressed to the Registrar, the Inner office of London, South Kensington, S W 7.

UNIVERSITY OF BIRMINGHAM

THIS university confers the ordinary medical and surgical degrees—M B, Ch B, M D, and Ch M—and also diplomas and degrees in State medicine and dentistry. It has a plan, too, by which, extending his study to six instead of five years, the M B, Ch B candidate may become a Bachelor in Science as well. Of the five years' curriculum, the first four must be spent, as a rule, at the university itself, the fifth being passed at any approved school or schools. Occasionally, however, the Senate will reduce the period of enforced residence to three years and exempt from the First M B (Part I) those who have passed elsewhere an examination considered to be its equivalent. A degree of Ph D is also conferred for research study in medicine under special regulations. Candidates must be graduates in medicine of a recognized university.

Students entering the Medical Faculty for the M B, Ch B degrees must have passed—

(1) Either (a) the matriculation examination of the Joint Board of the Universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham, or (b) some other examination recognized as equivalent to the matriculation. Candidates for medical degrees are recommended to take Latin and a science subject—chemistry or physics—at the matriculation examination, although these subjects are no longer compulsory. The matriculation examination of the Joint Board is held in July and September. The regulations and the list of examinations accepted in lieu thereof will be sent on application to the Secretary to the Board, Joint Matriculation Board, 315, Oxford Road, Manchester.

(2) A recognized pre-medical examination in the subjects of chemistry and physics—for example, the Higher School Certificate of the Joint Matriculation Board, or a candidate may attend courses for pre-medical year in the university, October to June, taking chemistry and physics, and biology (optional).

PROFESSIONAL EXAMINATIONS

The candidate for the M B, Ch B degrees has five examinations to pass. In the second and final examinations the candidate must pass in all the prescribed subjects or undergo the whole examination again.

The First M B (Part I) deals with elementary biology, and physical and organic chemistry. The First M B (Part II) deals with anatomy and physiology, and the student must pass in both simultaneously. The Second M B deals with pathology and bacteriology, materia medica, and pharmacy. The Third M B takes place at the end of the fourth year, the subjects being forensic medicine, toxicology, public health, and pharmacology and therapeutics.

Final M B—This comprises medicine, surgery, midwifery and diseases of women, ophthalmology, and mental diseases. The candidate, in addition to more ordinary certificates, must be prepared with a certificate of having acted as a post mortem clerk for three months, and received special instruction in anaesthetics and clinical instruction in diseases peculiar to women, asylum ward work, ophthalmology, venereal diseases, ear and throat and skin diseases, etc. In respect to ophthalmology he must show that he has learnt refraction work. He also has to present to the examiners reports by himself on six gynaecological cases, and certificates drawn up by himself regarding four actual cases of lunacy and notes on two others.

M D—An ordinary candidate for this degree must be a M B, Ch B of not less than one year's standing. He presents an original thesis for approval, and then passes a general examination in the principles and practice of medicine. From the latter the Board of Examiners may exempt a candidate whose thesis is of exceptional merit. The regulations respecting the Ch M are of the same general character. Subject to certain requirements as to special research or other post-graduate study, graduates of other universities may obtain the M D and Ch M in the same way as holders of the Birmingham M B, Ch B.

FEES

The fee for matriculation is £2 £2 10/- for pre-medical examination (if taken in university) and £2 10/- for each of the first four professional examinations. M B, Ch B degree fee £10. M D and Ch M examinations £12 10/- each. For further particulars application should be made to the Dean of the Medical Faculty, University of Birmingham.

UNIVERSITY OF BRISTOL

In the Faculty of Medicine the following degrees are conferred: Bachelor of Medicine and Bachelor of Surgery (M B and Ch B), Doctor of Medicine (M D), Master of Surgery (Ch M), Bachelor of Dental Surgery (B D S), and Master of Dental Surgery (M D S). There are also the following diplomas: diploma in public health (D P H), diploma in dental surgery (L D S) and diploma in veterinary State medicine. All candidates for degrees in medicine, surgery, and dentistry are required to pass an examination called the School Certificate Examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees and diplomas are open to men and women alike.

Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery—Candidates must be not less than 21 years of age and have pursued the courses prescribed by university regulations during not less than five years after passing the first examination in chemistry and physics, of which three shall have been passed in the university, and two of these three subsequent to passing the second examination. All candidates for the degrees of M B, Ch B are required to satisfy the examiners in the several subjects of three examinations.

The First Examination—The subjects of examination are chemistry (inorganic), physics, and biology, the courses pursued being those for the time being approved for the intermediate part of the B Sc curriculum. This part of the curriculum shall extend over one year. Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the First Examination and will be regarded as having completed one year of study.

The Second Examination—The subjects of examination are organic chemistry and elementary anatomy (Part I) and advanced anatomy and physiology (Part II). Parts I and II may be passed separately or together.

The Final Examination—The subjects of examination are materia medica and pharmacy, pharmacology and therapeutics, general pathology, morbid anatomy, and bacteriology (Part I), special pathology, forensic medicine, toxicology, and public health, obstetrics (including diseases of women), surgery (systematic, clinical, practical and operative), medicine (systematic, clinical, and practical including mental diseases) (Part II). The subjects included in Part II may be taken in two groups—namely, Group I surgery and obstetrics, Group II medicine, public health, special pathology, forensic medicine, and toxicology. Candidates may pass Parts I and II together or separately, and the two groups of Part II may likewise be taken together or separately. Forensic medicine and toxicology may be taken either with Part I or with Group II of Part II.

Degree of Doctor of Medicine—Candidates must be Bachelors of the university of not less than two years' standing as such, and may elect either (1) to pass an examination in general medicine, or (2) to pass an examination in State medicine, or (3) to present a dissertation. The candidate who elects to pass the examination in State medicine must hold a Diploma in Public Health of some university or college, and the candidate who elects to present a dissertation may be examined in the subject thereof.

Degree of Master of Surgery—Candidates shall be Bachelors of not less than two years' standing as such, during which period they shall have attended the surgical practice of an institution approved for the purpose. They shall pass an examination in surgical anatomy, pathology, and bacteriology, and operative, clinical, and general surgery, and present to the university a dissertation on some subject of surgery. The degree may be taken also in general surgery, and a special subject—for example, oto-rhino-laryngology, ophthalmology, and gynaecology.

Diploma in Public Health—Candidates must be at least 25 years of age, be fully registered medical practitioners of not less than two years' standing as such, and have passed the examination prescribed by regulation. The examination is divided into two parts.

UNIVERSITY OF DURHAM

To its own undergraduates, who may be of either sex, this university grants the degrees of Bachelor of Medicine and Bachelor of Surgery (M B, B S), and Doctor of Medicine (M D), Master of Surgery and Doctor of Surgery (M S and D Ch), Bachelor of Hygiene, Doctor of Hygiene and Bachelor of Dental Surgery and Master of Dental Surgery (B D S and M D S), it also grants diplomas in public health, psychiatry, and dental surgery. The university accepts the Durham University School Certificate Examination (if the required subjects are passed with credit) for matriculation purposes, but also accepts the tests of a considerable number of

other educational bodies as a full or partial equivalent. A list may be obtained on application. In addition to satisfying the matriculation requirements of the university, every student must (1) pass a pre-registration examination in physics and inorganic chemistry conducted or recognized by the university, and (2) be registered on the books of the General Medical Council. To become a graduate, however, at the university it is not necessary to pass the major portion of the five years' curriculum within its precincts. It is sufficient if, before he presents himself for his final examination, the candidate has passed at least one year in study at the University of Durham College of Medicine, Newcastle upon Tyne, including the practice of the Royal Victoria Infirmary in the same city. The earlier examinations may be passed while the student works elsewhere.

PROFESSIONAL EXAMINATIONS

There are four professional examinations for the M.B., B.S. degrees. The First, Second, and Third Examinations are held in March, June, and December, and the Final Examination in June and December. The first deals with biology and organic chemistry, the second with anatomy and physiology, the third with pathology, bacteriology, materia medica, pharmacology, therapeutics, and pharmacy, medical jurisprudence, and public health. At the final M.B., B.S. the candidate is examined in medicine and clinical medicine, surgery and clinical surgery, midwifery and diseases of women and children, clinical and practical gynaecology, and clinically in psychological medicine, diseases of the throat, nose, and ear, diseases of the skin, diseases of the eye, and diseases of children.

M.D.—A Bachelor of Medicine who wishes to proceed to this higher degree must be of at least two years' standing, and must comply with the regulations printed in the Calendar of the College of Medicine. If the candidate is not a M.B. of the university, he must be a practitioner of fifteen years' standing, 40 years of age, and submit to special tests. (See under Degrees for Practitioners, p. 439.)

M.S.—Candidates for this degree must have been engaged in practice for at least two years subsequent to becoming M.B., B.S. Durham. They are submitted to an examination which covers the whole range of surgical knowledge.

D.Ch.—The university grants also the degree of Doctor of Surgery. Candidates for this degree must be registered medical practitioners, not less than 24 years of age. They must devote three years, subsequent to obtaining a registrable qualification, to the study of surgery and auxiliary subjects, one at least of the three years must be spent in the university. The candidate must submit to the professor of surgery the course of study he proposes to follow, and this course must be approved by the Board of the Faculty of Medicine.

One year must be devoted mainly to work in the departments of anatomy, physiology, pathology, and bacteriology, and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as resident surgeon in a recognized teaching hospital, and the rest of the year in the study of surgery in a recognized medical centre. Not less than six months of one of the three years must be spent in surgical study abroad.

Degree of Bachelor of Hygiene and the D.P.H.

No candidate is admitted to the final examination for the degree of B.Hy. unless he is a Bachelor of Medicine and Surgery of not less than two years' standing of a recognized university.

No candidate is admitted to the final examination for the D.P.H. unless he is a registered medical practitioner of not less than two years' standing.

The course of study for the B.Hy. and D.P.H. extends over a period of not less than twelve calendar months subsequent to the attainment of a registrable qualification. Candidates for the B.Hy. must attend this course at the University of Durham. Candidates for the D.P.H. may attend it at the University of Durham or at any medical school or institution which is recognized by the university.

The examination for the diploma or degree consists of Part I and Part II each of which extends over not less than two days and is conducted by examiners specially qualified. A candidate must pass in all the subjects of Part I before being admitted to examination for Part II. In Part I and also in Part II, a candidate must pass in all the specified subjects at one time.

The examination for Part I is practical written and oral and includes the following subjects: bacteriology and parasitology (including chemistry and physics and relation to public health). Candidates are not admitted to examination for Part II until after they have completed the prescribed courses of instruction in the subjects thereof.

The examination for Part II includes the following subjects: hygiene and sanitation (including sanitary construction), epidemiology and infectious diseases, sanitary law and vital statistics, public health, examination is written and oral and includes the following subjects: infectious disease, food inspection, wellings, factories, workshop schools, etc. Candidates are not admitted to examination for Part II until after they have completed the prescribed courses of instruction in the subjects thereof.

Doctor of Hygiene

Candidates for the degree of Doctor of Hygiene must be Bachelors of Hygiene of two years' standing and are required to satisfy the examiners that they have conducted original research in the subject of public health.

Diploma in Psychiatry

Candidates must be registered medical practitioners and unless qualified before January 1st 1911 must have attended subsequently to passing their qualifying examinations, courses of instruction in (a) anatomy, (b) physiology, (c) pathology, (d) psychology and experimental psychology, (e) psychiatry, (f) clinical psychiatry. The diploma is of two parts namely (1) anatomy, physiology, pathology, and bacteriology, (2) psychology and experimental psychology, neurology, and psychiatry (systematic and clinical) and candidates may present themselves for the whole examination or for either part separately.

Licence and Degrees in Dental Surgery

D.S.—Every dental student must at the commencement of his studentship, be registered in the manner and under the conditions prescribed for medical students.

The first examination consists of three parts which may be passed separately. Part 1, organic chemistry, Part 2, biology, Part 3 theoretical dental mechanics, dental metallurgy (theoretical and practical). Second Examination: Anatomy, physiology, (including biochemistry and biophysics), dental anatomy and dental histology. Third Examination: Pathology and bacteriology, practical dental mechanics, dental materia medica and therapeutics. Final Examination: Medicine, surgery, dental surgery and pathology, orthodontics, operative dental surgery and dental prosthetics, and anaesthetics.

A candidate before presenting himself for examination is required to furnish certificates of instruction in the required subjects attended after registration as a dental student at recognized colleges or schools.

Degree of Bachelor of Dental Surgery—1—Students taking their complete course of instruction in the university must pass the same matriculation tests as medical students, and the same pre-registration examination in inorganic chemistry and physics. After registration students must spend five years in the university. They must attend the practice of the Newcastle upon Tyne Dental Hospital for not less than two and a half years, six months of this time must be devoted to the study of the higher branches of dental science. There are four examinations. The subjects of the examinations are as follows: First, Biology, organic chemistry, and dental mechanics and metallurgy. Second, Anatomy, physiology, dental anatomy and histology. Third, Pathology and bacteriology, dental materia medica and therapeutics, and practical and dental mechanics. Final, Medicine, surgery, dental surgery and pathology, orthodontics and operative dental surgery. In this subject knowledge of a much higher standard and more advanced practical work, are required than for the Licence in Dental Surgery.

2—Candidates possessing a Licence in Dental Surgery of a study for at least one year in the year they must (a) attend a course of and bacteriology and (b) spend at Newcastle upon Tyne Dental Hospital in the study and practice of the higher branches of dental science. They must also pass the third and final examinations for the degree of Bachelor of Dental Surgery.

Degree of Master of Dental Surgery—Every candidate for this degree must be a Bachelor of Dental Surgery of the university of not less than two years' standing and present an essay embodying original work and research in some subject connected with dentistry. He must also perform to the satisfaction of the examiners a piece of special dental work demanding a high degree of skill and experience.

The examinations are held concurrently with the medical examinations.

The practical examinations in dentistry are conducted at the Newcastle upon Tyne Dental Hospital.

FEES

The following fees are payable: Matriculation £2 Examinations, First Second and Third M.B., B.S. each £5 Final M.B., B.S. £15 M.D. and M.S. each £5 B.Hy. D.P.H. and D.Psy. each £10 10s. and D.Hy. and D.Ch. each £20 First Second and Third L.D.S. each £3 10s. and Final L.D.S. £5 First Second and Third B.D.S. each £5 Final B.D.S. £8 and M.D.S. £5 For degrees and diplomas M.B., B.S., B.Hy., and B.D.S., each £6 6s. plus

the sum of 10s. if it is the initial degree taken in the university, M S. and M D S., each £6 6s. M D. D Ch. and D H., each £10, D P H., D P S., and L D S., each £3

Further information may be obtained from Professor Howden, Registrar, University of Durham College of Medicine, Newcastle-upon-Tyne

UNIVERSITY OF LEEDS

The degrees granted in the Medical Faculty of this university are Bachelor of Medicine, Bachelor of Surgery (M B and Ch B), and Bachelor of Dental Surgery (B Ch D), Doctor of Medicine (M D), Master of Surgery (Ch M), and Master of Dental Surgery (M Ch D). It also gives diplomas in public health, in psychology, in dental surgery, and in nursing.

Candidates for the M B must have attended courses of instruction approved by the university for not less than five years, two at least of such years having been passed in the university, at least one year being subsequent to the date of passing the first examination. They must also have matriculated by satisfying the examiners in

- | | | |
|-----|---|---------------------------------|
| I | Either English Composition and English Literature or English Composition and History | |
| II | Either Mathematics or Latin | |
| III | Three other subjects not already taken under I and II above, chosen from the following list | |
| IV | | |
| 1 | English Literature | 9 Mathematics |
| 2 | History | 10 Mechanics |
| 3 | Geography | 11 Physics |
| | | 12 Chemistry |
| 4 | Greek | 13 General Experimental Science |
| 5 | Latin | 14 Natural History |
| 6 | French | 15 Botany |
| 7 | German | |
| 8 | Some one other language approved by the Board | |

Provided that (a) candidates who take Mathematics under II above must include one of the subjects 4-8. (b) candidates who take Latin under II above must include one of the subjects 9-15.

Exemption from the examination may be granted to applicants holding certificates of having passed examinations of a standard deemed by the Matriculation Board to be at least equal to the Board's examination.

PROFESSIONAL EXAMINATIONS

The examinations for the M B, Ch B number three. The first deals with (1) physics and chemistry, (2) biology. In each subject laboratory work is included, but the two parts can be taken separately. For neither can the candidate present himself until after matriculation and a period of approved work in the respective subjects.

Second M B—This examination may be taken in two parts: (a) anatomy and physiology, including practical work, (b) medical medicine and pharmacy, including actual compounding of drugs. The candidate's certificates must show, among other things, that he has dissected during at least five terms.

Final M B—This may be divided into three parts. The first (pathology and bacteriology) may be taken at the end of the fourth term, the second (forensic medicine and public health) and the third (medicine, surgery, obstetrics, and pharmacology and therapeutics) cannot be taken before the end of the fifth year, before admission to the examination in its subjects the candidate, besides ordinary certificates, must produce proof that he has done both intern and extern maternity work, and received clinical instruction in gynaecology, in diseases of the eye, skin or larynx and in the administration of anaesthetics. This division covers all branches of surgery, medicine (including mental diseases and diseases of children), and obstetrics and gynaecology. First and second class honours may be obtained in this division.

M D—A candidate for this degree must be a M B, Ch B of the university of at least one year's standing. He presents a dissertation embodying the results of personal observation or original research, and, if this is approved he may be required to write a short extempore essay on some topic connected with medicine, and may be examined orally on the dissertation or other work submitted.

Ch M—The candidate for this degree must have been admitted to the M B, Ch B of the university not less than

a year previously, and during that time must have held for at least six months a surgical appointment in a public institution affording full opportunity for the study of practical surgery. He must also have attended certain courses, including one on bacteriology, one on bacteriology, he is then of surgery in all its branches.

FEES

The matriculation fee is £2 and on readmission £1 10s. For each of the other examinations £6 (£7 for Ch M) and £3 on readmission. On conferment of the degree of Ch M £7 is payable, and £6 for the M D degree.

UNIVERSITY OF LIVERPOOL

This university, besides granting degrees in medicine (M B and M D) and in surgery (Ch B, M Ch Orth, and Ch M), gives degrees in dental surgery (B D S. and M D S.), a degree in hygiene (M H), and degrees in veterinary science (B V Sc, M V Sc, and D V Sc). Diplomas are awarded in dental surgery (L D S.), tropical medicine (D T M), tropical hygiene (D T H), public health (D P H), veterinary hygiene (D V H) and medical radiology and electrology (D M R E).

MATRICULATION

The Matriculation Examination is governed by the Joint Matriculation Board, 315, Oxford Road, Manchester, which accepts, under certain conditions, the tests of several other bodies as its equivalent. Chemistry and physics are essential pre-registration subjects.

PROFESSIONAL EXAMINATIONS

Candidates for the M B, Ch B degrees have three examinations to pass, the first including (1) chemistry, (2) physics, (3) biology (zoology and botany).

Second M B—This test covers (a) (1) anatomy, (2) physiology, including physiological chemistry and histology, and (b) (3) elementary bacteriology, (4) clinical chemistry, (5) general pathology. Candidates may present themselves in (a) and (b) separately.

Final M B—The subjects of the Final Examination are (a) (1) special pathology and morbid anatomy, (2) forensic medicine and toxicology, (3) public health, (4) pharmacology and general therapeutics, (b) (5) obstetrics and diseases of women, (6) surgery—systematic, clinical, operative, and practical—including ophthalmology, (7) medicine—systematic and clinical—including therapeutics, mental diseases, and diseases of children. Candidates may take Parts (a) and (b) separately, but Part (b) may not be taken until five years of study have been completed.

M D and Ch M—Candidates for these degrees must have received the M B and Ch B at least two years previously. Students holding equivalent degrees of other approved universities may become candidates for the M D degree after two years' study in the university or clinical school of the university. The M D candidate submits for approval a thesis covering original work in some branch of medicine or so-called science directly relative to medicine, together with, if desired, copies of published work. The M Ch candidate undergoes an examination. Other information concerning the diplomas of this university and its medical school will be found on page 432.

FELLOWSHIPS, SCHOLARSHIPS AND EXEMPTIONS

The university awards Fellowships annually to students of distinguished merit as follows:

- (1) John Rankin Fellowships in Anatomy, two each of the value of £120 tenable for two years.
- (2) Ethel Boyce Fellowship in Gynaecology, value £100 and tenable for one year open to fully qualified medical students of either sex.
- (3) John W. Garrett International Fellowship in Bacteriology, value £100 and tenable for one year.
- (4) Robert Gee Fellowship in Human Anatomy, value £100 and tenable for one year.
- (5) Holt Fellowships in Physiology and Pathology, two in number, value £150 each and tenable for one year.
- (6) Johnston Colonial Fellowship in Biochemistry, value £100 and tenable for one year.
- (7) Thelwell Thomas Fellowship in Surgical Pathology, value £150 and tenable for one year.
- (8) Lady Jones Fellowship in Orthopaedic Surgery, value £200 offered every two years.

There are in addition scholarships and exhibitions open to medical students.

VICTORIA UNIVERSITY OF MANCHESTER

This university grants the four ordinary degrees in medicine and surgery—M B and Ch B and M D and Ch M, a degree and diploma in dental surgery, a diploma in public health, a certificate in factory and in school hygiene, a diploma in psychological medicine, and a diploma in bacteriology. Candidates for degrees must pass the special Matriculation Examination prescribed by the Faculty of Medicine (or some equivalent examination accepted in lieu thereof, see the prospectus of the Joint Matriculation Board), and study at the university itself for at least two years of the six years' curriculum, subsequent to the passing of the First M B Examination. The Matriculation Examination comprises (1) Latin, (2) mathematics, (3) the English language, its literature and history, (4) mechanics, (5) two subjects at choice as approved by the Joint Board. It is held in July and September.

PROFESSIONAL EXAMINATIONS

M B, Ch B—There are four examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. The first M B is divided into Part I, chemistry and physics, Part 2, biology—(a) botany, (b) zoology. The parts may be taken separately or together. At the second M B the candidate is examined in anatomy (including histology) and physiology, at the third, in pathology and pharmacology (including materia medica and practical pharmacy). The Final Examination is divided into two parts, which may be taken separately, and includes medicine (systematic and clinical), mental diseases, and diseases of children, surgery (systematic, clinical, and practical), obstetrics and gynaecology, preventive medicine, forensic medicine, and toxicology.

M D—A candidate for this degree must be a bachelor of medicine of at least one year's standing. He has a choice between presenting an original dissertation or undergoing a written (as well as practical and clinical) examination in medicine, and a written and practical examination in pathology, and one other subject selected by himself.

Ch M—A candidate must have held, since becoming Ch B, and for not less than twelve months, a post in a public institution affording opportunity for the study of the branch of surgery in which examination is desired. The examination in Branch I comprises the general field of surgery, Branch II, obstetrics and gynaecology, Branch III, ophthalmology, Branch IV, otology, laryngology, and rhinology.

FEES

The following examination fees are payable. Matriculation £2, on readmission £1 10s. Each M B examination £8 8s., on re-admission, £3 3s. M D including the conferring of the degree, £15 15s. Ch M, £6 6s. for the examination and £9 9s. for conferring of degree. Application for further information should be addressed to the Dean of the Medical Faculty.

UNIVERSITY OF SHEFFIELD

The degrees of this university (M B, Ch B, M D and Ch M, B D S, and M D S), the diploma in public health, and the diploma of licence in dental surgery, are open to candidates of either sex. Candidates for a degree must have matriculated in the university or have passed such other examination as may be recognized for this purpose, and have passed the further examination in chemistry and physics.

PROFESSIONAL EXAMINATIONS

A candidate for the degrees of M B, Ch B must produce certificates that he will have attained the age of 22 years by the day of graduation, that he has pursued the courses of study required by the university regulations during not less than five years subsequent to the date of his matriculation or exemption from matriculation, and the passing of the further examination in chemistry and physics, three of such years at least having been passed in the university, one at least being subsequent to the passing of the First Examination. The following examinations must be passed in due order.

First Examination—The subjects are chemistry, physics, and biology. Candidates who have passed the Intermediate Examination of the Faculty of Pure Sciences in any or all

of the subjects of the First M B Examination, will, on payment of the fee for the latter examination, be deemed to have passed it when they have passed in such subjects as they did not take for the Intermediate B Sc Examination. Candidates on presenting themselves for this examination are required to furnish certificates of having attended for not less than one year approved courses of instruction, after matriculation, and the passing of the further examination in physics and chemistry, in (i) chemistry, inorganic and organic, (ii) physics, (iii) biology.

Second Examination—The subjects are anatomy and physiology. The candidate must have completed the second year of professional study, must have passed the First Examination, and must have attended (1) lectures on anatomy and dissections during three terms, (2) lectures on practical, experimental, and chemical physiology and histology during three terms.

Third Examination—The subjects are pathology and pharmacology, anatomy, and physiology. Candidates must have completed the fourth winter of medical study and the requisite courses in these subjects, including *post mortem* dissection for three months.

Final Examination—The subjects are—Part I, forensic medicine and public health, Part II, medicine (including mental diseases and diseases of children), surgery, obstetrics (including gynaecology). Candidates must have completed the fifth year of study.

M D—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M B, Ch B at least one year previously, must present a thesis embodying observations in some subject approved by the Professor of Medicine, and must pass an examination in the principles and practice of medicine.

Ch M—Candidates for the degree of Master of Surgery must have passed the examination for the degrees of M B, Ch B at least one year previously, and must, since taking the degrees of M B, Ch B, have held for not less than six months a surgical appointment in a public hospital or other public institution affording full opportunity for the study of practical surgery. The subjects of examination are systematic, clinical, and operative surgery, surgical anatomy, surgical pathology, and bacteriology.

Other information concerning this university will be found in the section devoted to Provincial Medical Schools.

UNIVERSITY OF WALES

The Charter and statutes of the University of Wales provide *inter alia* for a Faculty of Medicine and for the granting of the following degrees: Bachelor in Medicine (M B), Bachelor in Surgery (B Ch), Master in Surgery (M Ch), and Doctor in Medicine (M D).

A candidate for the M B, B Ch is required to pursue a course of study of not less than six academic years subsequent to matriculation in the university, and of these years at least three must have been passed in one of the constituent colleges of the university. These are the University College of Wales, Aberystwyth, University College of North Wales, Bangor, University College of South Wales and Monmouthshire, Cardiff, and University College, Swansea. He must also hold an arts or science degree of the University of Wales, or of some other university approved for this purpose. Certain of the courses of study pursued for a B Sc or B A degree may be counted as courses required for the degrees in the Medical Faculty.

The courses for the M B, B Ch are divided into two sections, of which the first includes the preliminary subjects—physics, chemistry, botany, zoology, and the ancillary subjects—organic chemistry, human anatomy, and physiology. Study of the preliminary subjects and of organic chemistry must extend over at least one academic year, study of physiology and anatomy must extend over at least two academic years, the first section of the course must occupy not less than three years, the second section includes courses in pathology, bacteriology, pharmacology, hygiene and forensic medicine, medicine, surgery, and obstetrics and gynaecology, and cannot be commenced, except in the case of pharmacology, until the examinations relating to the preliminary and ancillary courses have been

passed Examinations in all the subjects are held in June of each year.

The university also offers courses of study in public health and in tuberculosis. Candidates for the Diploma in Public Health (D.P.H.) and for the Tuberculous Diseases Diploma (T.D.D.) must possess a medical qualification registrable for practice in Great Britain and Ireland, and must have completed courses of study as prescribed by the regulations either at the Welsh National School of Medicine, Cardiff, or at another institution approved by the university.

WELSH NATIONAL SCHOOL OF MEDICINE

Students can complete the whole of their curriculum in the Welsh National School of Medicine, which is an integral part of the University College of South Wales and Monmouthshire, and qualify for the degrees of M.B., Ch.B. in the university.

Further information may be obtained from the Registrar, the University Registrar, Cathays Park, Cardiff.

English Medical Corporations.

THERE are in England three medical corporations which grant licences to practise—the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The first two combine for certain purposes to form what is known as the Conjoint Board in England. Details concerning this body, its component Colleges, and the third licensing body here follow.

THE CONJOINT BOARD

THIS body—the Examining Board in England—deals with the qualifications of all candidates for the Licence of the Royal College of Physicians of London and for the Membership of the Royal College of Surgeons of England. It prescribes for them certain periods of study, and recommends those who pass the required examinations for the Licence and for the diploma of Member respectively. The successful candidate is then entitled to register as L.R.C.P. Lond., M.R.C.S. Eng. It performs the same task in connexion with diplomas in public health, tropical diseases, ophthalmic medicine and surgery, psychological medicine, and laryngology and otology—jointly issued by the two Colleges in question. Under the new regulations, which apply to all students who have not passed the required preliminary tests of general education before January 1st, 1923, every candidate for the M.R.C.S. and L.R.C.P. must (1) complete five years of professional study after passing a recognized preliminary examination and a recognized pre-medical examination in chemistry and physics, (2) comply with the regulations, which may be had from the Secretary, Examination Hall, Queen Square, Bloomsbury, London, W.C.1, and (3) pass the two professional examinations of which particulars appear below. The old regulations for the Conjoint diploma, of which an account was given in the Educational Number for 1922, still apply to students who passed their preliminary examination in general education before January 1st, 1923.

NEW REGULATIONS FOR THE CONJOINT DIPLOMA

The following is an outline of the regulations applicable to candidates for the L.R.C.P. Lond. and M.R.C.S. Eng., who passed the required Preliminary Examination in general education on or after January 1st, 1923. The full regulations and synopses and forms of certificate may be obtained from the Secretary.

PRE-MEDICAL EXAMINATION

Students are required to pass a pre-Medical Examination in Chemistry and Physics conducted by the Conjoint Examining Board. The curriculum of professional study recognized by the Board—namely the and Physics for the degree in Medicine of any university recognized by the Board, the Higher School Certificates of Oxford and Cambridge Universities and the Oxford and Cambridge Schools Examination Board, the Higher Certificates

of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, and the Central Welsh Board Higher Certificate.

A candidate must enter for Chemistry and Physics together and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required Preliminary Examination in General Education and of having received instruction during 180 hours in Chemistry and 120 hours in Physics to the satisfaction of his teachers. These courses may be commenced or attended before the required Preliminary Examination in General Education is passed.

The examination is partly written, partly oral and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months and he must produce evidence of further instruction in the subject or subjects of failure.

PROFESSIONAL EXAMINATIONS

There are two Professional Examinations called the First and Final Examinations. The courses of study for these examinations must not be commenced until the Pre-Medical Examination in Chemistry and Physics or some equivalent examination has been passed.

First Professional Examination.—The subjects of this are Section I, (a) Anatomy, including Histology and Embryology, (b) Physiology, including Biochemistry. Section II, Pharmacology, Practical Pharmacy and Materia Medica. A candidate must have attended at a recognized Medical School courses of instruction in Anatomy, including Embryology during five terms during which he must have dissected the whole body courses of instruction in Physiology, including General Biology, Biochemistry, and Bio-physics during five terms courses of instruction in Pharmacology, Practical Pharmacy, and Materia Medica. A candidate may present himself for the two Sections together or separately, but he must take parts (a) and (b) of Section I together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part. Section II of the examination may be passed at any time before the candidate enters for the Final Professional Examination. A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I or of either part of Section I and of Section II in the examination for the degree in Medicine conducted at a university recognized by the Board will be exempted from further examination in such subject or subjects.

Final Professional Examination.—The subjects of this are Section I, (a) Pathology, including Morbid Anatomy, Morbid Histology and Clinical Pathology, (b) Bacteriology. Section II, Part I, Medicine, including Medical Anatomy, Forensic Medicine and Public Health. Part II, Surgery, including Surgical Anatomy and the use of Surgical Appliances. Part III, Midwifery and Gynaecology. The examination is partly written, partly practical, partly clinical and partly oral. A candidate may take Sections I and II and the three parts of Section II of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates required by the regulations before being admitted to the respective parts of the examination. A candidate who produces evidence of having passed an examination for a degree in Medicine in the subjects of Pathology and Bacteriology at a university recognized by the Board is exempted from Section I.

FEES

The fee for the Pre-Medical Examination is three guineas, for re-examination in Chemistry two guineas, and for re-examination in Physics one guinea. The fee for the First Professional Examination is ten guineas for re-examination after rejection in Section I six guineas for re-examination after rejection in either part of Section I three guineas for re-examination after rejection in Section II three guineas. The fee for admission to Section I of the Final Professional Examination is four guineas, for admission to Section II Part I ten guineas Part II ten guineas Part III six guineas and the re-examination fees are respectively three guineas, six guineas, and four guineas.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

THIS College has three grades—its Licentiates, its Members, and its Fellows. The Licence is now only issued through the Conjoint Board. The Membership is only granted to those who have passed the final examinations for the Licence, or those who are registered practitioners and graduates of a recognized university, in any case they must be persons over 23 years of age. Candidates are examined in pathology and the practice of physic, partly in writing and partly viva voce, they are also examined in Latin, Greek, French, and German. The languages are not compulsory, but credit is given to those who show a knowledge of them. The fee for the Membership is £42, or in the case of a Licentiate £21. There is a fee of £6 6s. payable before entrance to the examination, which in the case of successful candidates is reckoned as part of the Membership fee. The body of Fellows is maintained by election from among the Members.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

This College has two grades—Members and Fellows. The Members are admitted as stated in the section dealing with the Conjoint Board. The Fellowship is granted after examination to persons at least 25 years of age who have been engaged in professional studies for six years. There are two examinations for the Fellowship—the first in anatomy and physiology, which may be passed after the third winter session, the second, chiefly directed to surgery, which may be passed after six years of professional study. Candidates must pass the Final Examination of the Examining Board in England and be admitted Members of the College before admission to the Second Examination for the Fellowship, except in the case of graduates in medicine and surgery of not less than four years' standing of universities recognized by the College for the purpose, who are required to attend for one year the surgical practice of a general hospital recognized by the College after obtaining their degrees.

Fees.—At first examination £8 8s. for re-examination £5 5s. At second examination £12 12s. Diploma fee for non-members, £10 10s.

SOCIETY OF APOTHECARIES OF LONDON

This body confers a registrable diploma in medicine, surgery, and midwifery, now known as the L.M.S.S.A. (Licentiate in Medicine and Surgery of the Society of Apothecaries), on those successful at the following examinations.

Primary Examination—This is divided into two parts, of which Part I includes chemistry, chemical physics, practical chemistry, biology, and pharmacy. Part II includes anatomy, physiology, and histology, and cannot be passed before the completion of twelve months' practical anatomy with demonstrations. Candidates will be excused any or all the subjects of the primary examination on producing evidence that they have passed equivalent examinations before an examining body recognized by the Society. Candidates referred in anatomy will be required to produce evidence of further work in the dissecting room before being admitted to re-examination.

Final Examination—This is divided into three parts. Part I includes clinical surgery, the principles and practice of surgery, surgical pathology, operative manipulation, surgical anatomy, instruments and appliances. Part II includes clinical medicine (a) the principles and practice of medicine (including therapeutics, pharmacology, and prescriptions), pathology, and morbid histology, (b) forensic medicine, hygiene, theory and practice of vaccination, and mental diseases. Part III includes midwifery, gynaecology, and diseases of newborn children, obstetric instruments and appliances.

The fee for the primary examination is £5 5s. for the final £15 15s. The regulations and synopsis relating to the several examinations and other information may be obtained from the Secretary Court of Examiners, Apothecaries Hall, Blackfriars, E.C.4.

The Scottish Universities.

THERE are in Scotland four universities, each possessing a faculty of medicine, and having the right to confer degrees which admit the holder to the *Medical Register*. In essential points the regulations in their medical faculties for undergraduates are much alike, so that a general account can be given of all of them together.

The universities are those of Edinburgh, Glasgow, Aberdeen, and St. Andrews. The provision each of the cities in which these universities are situated makes for the education of medical students will be found in the section on Medical Schools in Scotland, here it need merely be said that degrees in medicine from Scotland as a whole have always enjoyed a high repute.

The degrees granted in medicine and surgery to candidates of either sex are four in number—Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.). The two former are not obtainable one apart from the other. Besides these

degrees a diploma in tropical medicine and hygiene is obtainable from the University of Edinburgh, and diplomas in psychiatry and public health. As for public health, registrable degrees in this subject are granted by the universities of Edinburgh and Glasgow, while diplomas in public health may be obtained from the universities of St. Andrews and Aberdeen.

The conditions for admission of graduating students of medicine are the same as those in the Faculties of Arts or Science (for degrees in pure science).

As from January 1st 1923 prospective medical students are also required to pass a pre-registration examination in chemistry and physics.

PROFESSIONAL EDUCATION

The regulations comply in all respects with the requirements and recommendations of the General Medical Council, and, in addition, necessitate definite study for stated periods of diseases of children, of the larynx, ear, and nose, of the skin, of ophthalmology, and of mental diseases. In respect of the various courses certificates must be obtained showing that the student has not only attended regularly, but has actually performed the work of the class. Out of the necessary five years of medical study, not less than two must be spent at the university whose degrees the student hopes to obtain, and the balance at any place officially recognized for such purpose. In each academic year there are two sessions—one lasting from the beginning of October to the middle of March, and the other from the beginning of May to the middle of July.

PROFESSIONAL EXAMINATIONS

The distinctive feature of the Scottish curriculum is that, though nominally there are only four examinations, each of these may be, and habitually is, split up by the student into sections. Hence, a student may complete some stage of his career during the course of nearly every session. Thus by the end of the first winter session the student may pass in zoology and chemistry. At the end of the first summer session he can finish with botany and physics and with anatomy and physiology at the end of the second. Pathology and materia medica he will pass at the end of the third year, and so on, until the final examination in midwifery, surgery, and medicine, and the corresponding clinical subjects, at the end of the fifth year of study. At each examination the candidate may pass "with distinction," and a record is kept of the merit displayed, so that, when the time comes for the candidate to graduate, one who has done well throughout can be declared as graduating with first or second class honours. A further point in the system is that the student's own teachers commonly take some part in his examination.

Of the four examinations, the first deals with physics, botany, zoology, and chemistry, the second with anatomy and physiology, the third with materia medica and pathology, the fourth with medicine and surgery (clinical and systematic), midwifery, clinical midwifery, and clinical gynaecology, and forensic medicine and public health. The first three examinations are held three times a year, the final twice a year.

Exemption from the first professional examination can be obtained by candidates who have passed an arts or science degree examination in its subjects at any recognized university. When a candidate presents himself for an examination in several of its parts but is not successful in all of them, he is credited at the next examination with those subjects in which he has already been approved.

THE HIGHER DEGREES

It is open to those who are already M.B., Ch.B. to proceed either to the M.D. or the Ch.M. A candidate for the former must have been engaged for not less than one year in work in the medical wards of a hospital, or in scientific research in a recognized laboratory, or in the Naval or Military Medical Services, or have been at least two years in general practice, and he must be 24 years of age. He has to write a thesis on any subject not exclusively surgical, and is examined in clinical medicine and in some one or other of its special departments. The regulations for candidates for the Ch.M. are of a corresponding character,

a period of surgical work in a hospital or elsewhere being substituted for medical work, and the thesis being on a surgical rather than a medical subject. He is examined in surgical anatomy, clinical surgery, operative surgery, and in some of the special departments of surgery.

FEES

It is estimated that the class examination and other fees for the M B Ch B come altogether to about £247, the separate examination fees included in this calculation being as follows:

First Professional	£	s	d
Second Professional	9	9	0
Third Professional	7	7	0
Final	6	6	0
	11	11	0

Re entry in any subject in which the candidate has failed entails a fresh payment of £1 1s. Candidates for the M D and Ch M pay £21, and on re entry £5 5s.

More detailed information with regard to the University of Edinburgh can be obtained from the *Medical Programme*, price 6d, which is published by Mr. Thun, 55, South Bridge, Edinburgh, or on application to the Dean of the Faculty of Medicine. Similar information about Glasgow should be sought from the Assistant Clerk, Matriculation Office, Glasgow. With regard to Aberdeen, application may be made to the Secretary of the Medical Faculty, Marischal College. In respect of St. Andrews information can be obtained either from the Secretary of the University, or, alternatively, the Secretary of the United College, St. Andrews, or the Secretary of University College, Dundee, these being the two constituent colleges of the University of St. Andrews.

Finally, it should be mentioned that in connection with all the Scottish universities there are valuable bursaries and scholarships, some information as to which will be found in the article on Medical Schools.

THE CARNEGIE TRUST

The following is a summary of the regulations made by the Carnegie Trust for the universities of Scotland for assistance in the payment of class fees in the universities and extra mural colleges of Scotland.

Applicants must be over 16 years of age; they must be of Scottish birth or extraction or have attended for two years after the age of 14 at a school or institution under inspection of the Scottish Education Department. Applicants so qualified who have been pupils of schools under the Scottish Education Department will be eligible for assistance in the payment of class fees if they have obtained the leaving certificate of the Department provided that it bears evidence of such preliminary education as is required by the universities for their graduation curricula or that it has been supplemented by such passes either in the Scottish Universities Preliminary or other examination as will satisfy the above requirement of the universities. Where applicants have not been pupils of schools under the Scottish Education Department or where other good ground for not having obtained the leaving certificate can be shown the Executive Committee has power to accept instead what it deems equivalent evidence of attainments.

Applicants in the Faculties of Arts and Science must have had their course of study for each academic year approved by the University Adviser of Studies and they must have passed the graduation examinations belonging to the previous stage of their curriculum before becoming eligible for assistance in the payment of fees of classes belonging to a further stage. Beneficiaries must submit to the Executive Committee at the end of each session particulars as to their attendance and work, any distinctions gained and any graduation examinations passed.

The annual allowance towards payment of class fees offered to beneficiaries by the Trust in the Faculty of Medicine is £19 for four years in all £76. Any unexpended part of a grant will be carried forward to the succeeding year. In combinations of Faculties the allowances available for beneficiaries are Arts and Medicine—two Arts grants of £8 and four Medicine grants of £19 in all £82. Science and Medicine—two Science grants of £17 and four Medicine grants of £19 in all £110.

Applicants in writing for application forms must name the university and faculty in which they intend to study and state whether they have previously obtained the benefits of the Trust. Applications must be lodged not later than October 25th for the winter session or May 10th for the summer session. Payments are made by means of fee coupons and fees already paid are not refunded.

The Scottish Corporations.

THERE are three medical corporations in Scotland—the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Their licences can be separately obtained only by persons who are already in possession of a recognized qualification—in surgery in the case of the College of Physicians, and in medicine in the case of the College of Surgeons and the Faculty of Physicians and Surgeons of Glasgow. All others must submit to the examinations held by the Conjoint Board which the three corporations have combined to form. Details concerning this Board and its component colleges follow. The conditions on which their higher qualifications are granted will be found set forth separately in connection with each corporation.

THE CONJOINT BOARD IN SCOTLAND

THIS body has charge of all questions connected with candidates for the Conjoint Licences of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Those finally approved by it are entitled to registration and to the initials denoting the Licences of the three bodies concerned—namely, L R C P Edin, L R C S Edin, and L R F P S Glasg. The Board requires all candidates to comply with the regulations of the General Medical Council. It has an arts examination of its own, but is prepared to accept in its place any of the other educational tests approved by the General Medical Council. All candidates must obtain registration with the General Medical Council.

Professional Curriculum for Candidates registered as Medical Students prior to January 1st, 1923

Subsequent to registration as a medical student the candidate must pass not less than five years in medical study, each comprising a winter and a summer session. The Board does not insist that candidates shall pursue their study at any particular place, and is prepared to accept certificates of having attended the necessary courses from any recognized medical school.

Its examinations are four in number, each of them being held four times every year, and these will fall to be held twice in Edinburgh and twice in Glasgow during the next period, it is open to candidates to present themselves for examination at either place. The first examination deals with physics, chemistry, and elementary biology, the second with anatomy and physiology, including histology, the third with pathology and materia medica, including pharmacy, and the final with (1) medicine, including therapeutics, medical anatomy, and clinical medicine, (2) surgery, including surgical anatomy, clinical surgery, and diseases and injuries of the eyes, (3) midwifery and diseases of women and of newborn children, including clinical gynaecology and practical midwifery, and, if it has not been passed previously, (4) medical jurisprudence and hygiene. Candidates may also be examined on diseases of children, diseases of the ear and throat, insanity, vaccination, etc.

These examinations must be passed in due order, and before admission to any of them the candidate must supply certificates showing that he has completed the due periods of study of their subjects. He can present himself in any single subject of the first three examinations. As regards the final examination, a candidate can present himself in medical jurisprudence and hygiene at any time after completion of the third examination and of his study of these subjects, but in medicine, surgery, and midwifery he cannot present himself until the completion of five years' study, and he must take them all simultaneously. A candidate who takes up several subjects of an examination or the whole of the subjects at one time, but fails in some of them, is credited at the next examination with those subjects in which he has been approved.

Part or entire exemption from the first three examinations may be granted to those who have already passed before other bodies examinations deemed by the Board equivalent to its own, but all candidates for the Conjoint licence must sit for the final examination, and at no examination can a candidate present himself within three months of his rejection by some other licensing body.

Professional Curriculum for Candidates registered as Medical Students after January 1st, 1923

The curriculum has been extended to meet the recommendations of the General Medical Council. Candidates when applying for copies of regulations should state date of medical registration.

FEES

It is estimated that the total cost of lectures and fees for the Conjoint licence is about £152. The separate examination fees are as follows: First Second and Third Professional £5 each; Final £15. On re-entry for any of the first three examinations £3 and on re-entry for the Final £5. If the re-entry is only in one or two subjects the fees are smaller.

Information concerning this Board should be sought either from Mr D. L. Laidie, 49, Lauriston Place, Edinburgh, or from Mr Walter Hirst, Faculty Hall 242, St Vincent Street, Glasgow.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

This College has three grades—Licentiate, Membership, and Fellowship—all of which are open to men and women. The regulations applying to candidates for the Licentiate have already been generally indicated. If desirous of receiving it apart from those of the other two corporations they must be holders of a surgical qualification recognized by the College, and must pass an examination corresponding to the medical part of the Final Examination of the Conjoint Board and conditioned in the same way, and also an examination in medical medicine. The fee for examination is 15 guineas, a special examination being obtainable on due cause being shown, and on payment of 5 guineas extra. Ordinary examinations take place monthly on the first Wednesday and Thursday, except in September and October. Candidates for the Membership must be either Licentiates of a British or Irish College of Physicians, or alternatively graduates of medicine of a university approved by the Council, and in either case not less than 24 years of age. Candidates are examined in medicine and therapeutics, also on one or more departments of medicine specially professed, and approved by the Council, in which a high standard of proficiency will be expected. The fee to be paid by a candidate for the Membership is £36 15s. The examination is held quarterly, and application for admission to it must be made a month previous to its date. For the Fellowship the candidate must have been a Member of the College for at least three years, and if accepted, pays fees, including £25 stamp duty, amounting altogether to £64 18s. Further details can be obtained on application to the Secretary of the College.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

This College has two grades—its Licence and its Fellowship. Licentiates may be of either sex, and for the Fellowship women are eligible also.

Licence

As an original qualification the Licence is only granted after fulfilment of the regulations of the Conjoint Board, but as an additional qualification it can be obtained by those already possessed of a registrable qualification in medicine. In this case the candidate has to pass a written, oral and clinical examination in surgery and surgical anatomy, and may be asked to operate on the dead body.

The fee is £15 15s. of which £10 10s. is returned to unsuccessful candidates. On due cause being shown a special examination may be granted the fee being £20 of which £10 is returned to a candidate if he is not approved.

Fellowship

Candidates for the Fellowship must be not less than 25 years of age, and have been in the practice or study of

their profession subsequent to registration for at least two years, and must hold either a surgical degree from a university recognized for that purpose by the College, or a registrable diploma obtained as the result of an examination which includes surgery as well as medicine and midwifery. Candidates are examined in (a) the principle and practice of surgery, including surgical anatomy, (b) clinical surgery, and (c) one optional subject, which they may choose from among the following: surgical pathology and operative surgery, ophthalmology, laryngology, otology, and rhinology, gynaecology, obstetric surgery, midwifery, and dental surgery and pathology. The examination is written, oral, and clinical or practical. A candidate who desires to be examined must give one month's notice, his application for admission being supported by two Fellows of the College, one of whom must be resident in Edinburgh, or, in default, by testimonials specially obtained for the purpose. Candidates are not allowed to appear more than three times at the examinations.

Licentiates of the College pay £35 and others £45. For further information application should be made to the Clerk of the College Mr D. L. Laidie, 49, Lauriston Place, Edinburgh.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

This body possesses two classes—Licentiates and Fellows. The regulations applying to the former correspond with those respecting candidates for the Licence of the Royal College of Surgeons of Edinburgh. Candidates for the single Licence are examined in surgery (including clinical surgery and surgical anatomy). The fee is £15 15s. and examinations are held quarterly. Candidates for the Fellowship must be qualified medical men of not less than two years standing, and 24 years of age. Candidates approved at this examination are then eligible for election as Fellows. Special regulations are in force for medical practitioners who served in the late war. The Faculty can also elect from Fellows annually without previously submitting them to examination, providing they "have highly distinguished themselves in medical science or practice." They must be of not less than ten years' standing and 40 years of age.

The fee for the Fellowship is £50. Further information can be obtained from Mr Walter Hirst, Faculty Hall 242, St Vincent Street, Glasgow.

The Irish Universities.

There are three universities in Ireland, each with a medical faculty. These are, in the Irish Free State, the University of Dublin (usually known as Trinity College, Dublin), and the National University of Ireland, and, in Northern Ireland, the Queen's University of Belfast. The Universities of Dublin and Belfast teach students, examine them, and grant degrees, the National University of Ireland is an academic body only, inasmuch as its practical work is divided among three constituent colleges situated, one at Cork, another at Galway, and the third in Dublin. Information as to the arrangements for the education of medical students will be found in the section relating to Irish Medical Schools.

UNIVERSITY OF DUBLIN TRINITY COLLEGE

This university grants two degrees in medicine (M.B. and M.D.), two in surgery (B.Ch. and M.Ch.), two in midwifery (B.A.O. and M.A.O.), and a post-graduate diploma in public health. It also grants a post-graduate diploma in gynaecology and obstetrics, for which nine months' study is required. The degrees are granted to those who, having passed the Professional Examination, have also graduated in arts.

PROFESSIONAL EXAMINATIONS

A candidate for the Final Examination for the M.B., B.Ch., and B.A.O. degrees must be a matriculated student of at least five years' standing. The examinations which students must pass are the Preliminary Scientific, the Intermediate Medical, and the Final. Before admission to

any of these examinations students must have completed the courses of study in the subjects involved

Preliminary Scientific—This covers (a) chemistry, (b) physics, (c) botany and zoology, the three divisions may be taken together or at different times

Intermediate Medical—This is divided into two parts: (a) anatomy, physiology, organic chemistry, and histology, (b) applied anatomy and applied physiology. The two parts may be taken separately or together

Final Examination—Part I Hygiene and medical jurisprudence, pathology and bacteriology, materia medica, and therapeutics. Part II (a) Midwifery and gynaecology, (b) medicine and mental diseases, (c) surgery in all branches, including clinical ophthalmology. The three sections of Part II may be taken separately or together. In either case the full curriculum must have been completed, and the final examination cannot be completed before the end of the fifth year

M D—The candidate must have passed all the qualifying examinations in medicine, surgery, and midwifery, and have taken, or have been qualified to take, the degree of B A three years previously. He must send in a thesis for approval. Subsequently the Regius Professor of Physic and an assessor will discuss with him questions connected with the thesis, and may also examine him *viva voce* on other medical subjects of a more general nature

M Ch—The candidate must be a B Ch of not less than three years' standing, and have been engaged in practice for two years

M A O—The candidate must be a B A O of not less than two years' standing and must produce satisfactory evidence of having been engaged for two years in obstetric science. The examination is specially directed to obstetrics and practical gynaecology

Further information regarding courses of instruction, etc., may be obtained from the Registrar of the School of Physic, Trinity College, Dublin

QUEEN'S UNIVERSITY, BELFAST

The degrees granted by the Medical Faculty of this university are as follows: Bachelor of Medicine (M B), Bachelor of Surgery (B Ch), Bachelor of Obstetrics (B A O), Doctor of Medicine (M D), Master of Surgery (M Ch), Master of Obstetrics (M A O). The university also confers a Diploma in Public Health. The first three degrees mentioned serve as a qualification for admission to the *Medical Register*, and are not granted separately. In addition to matriculating and passing his professional examinations, a candidate for these degrees must have passed three of the regulation five years as a student at the Belfast School of Medicine. Degrees in dental surgery (B D S and M D S) are conferred by the university, and also a diploma in dental surgery (L D S)

PROFESSIONAL EXAMINATIONS

The examinations for the M B, B Ch, B A O are four in number. The first deals with (1) inorganic, organic, and practical chemistry, (2) experimental and practical physics, (3) botany and practical botany, (4) zoology and practical zoology. It is divided into two parts, of which botany and zoology form one. The Second Examination covers anatomy and physiology, and may be taken at the end of the second year of the student's career. The Third Examination includes (1) pathology, (2) materia medica, pharmacology, and therapeutics, (3) medical jurisprudence, and (4) hygiene. To be valid a certificate in regard to the study of the subjects of this examination must show that the work has been done after the First Examination has been passed

The Final Examination includes (1) medicine, (2) surgery, (3) midwifery, (4) ophthalmology and otology. The student may pass in all subjects at once at the end of his fifth year, or he may divide the examination into two parts—namely, (1) systematic, (2) clinical, practical, and oral. The first part may be taken at the end of the fourth year, but for the second part the candidate may not present himself until the end of his fifth year, but students invariably take both parts at the end of their course. No certificate in regard to the study of the subjects of this examination will be valid unless the work was done subsequent to passing in all the subjects of the Second Examination

THE HIGHER DECREES

Candidates for the degree of Doctor of Medicine must be graduates in medicine of at least three years' standing, unless they hold also a degree of the university in arts or science, in which case a standing of two academic years will suffice. Moreover, candidates must be able to show that the interval has been passed in the pursuit of such courses of study or practical work as may be prescribed. The degree may be conferred either (a) after a formal examination, or (b) in recognition of the merits of a thesis or of some piece of original study or research carried out by the candidate, followed by an oral or other examination in its subject. When an ordinary examination is imposed it will include (1) a written paper on the principles and practice of medicine, (2) a commentary on a selected clinical case, (3) a clinical and *viva voce* examination, and (4) a written paper and clinical or practical and *viva voce* examination on a subject chosen from the following list: (a) human anatomy, including embryology, (b) physiology, (c) pathology, (d) pharmacology and therapeutics, (e) sanitary science and public health, (f) forensic medicine and toxicology, (g) mental diseases. The regulations for the degrees of M Ch and M A O are of the same general nature

NATIONAL UNIVERSITY OF IRELAND

The National University of Ireland carries on most of its educational work through three constituent colleges—one in Dublin, one in Cork, and one in Galway. Each of these provides a full medical curriculum, and all candidates for the medical degrees of the university must pass three of their five years of study at one or other of them. These years do not count except after matriculation or recognition as a student of the Medical Faculty obtained in some other fashion. The candidates at each constituent college are examined there by the university, and a common standard of education is secured by all courses of instruction and the regulations concerning them having to be approved by the Senate, after considering report thereon from the Board of Studies of the university. In addition to the ordinary degrees in medicine and surgery, the university grants those of Bachelor and Master of Obstetrics, Bachelor and Doctor of Science in Public Health, and Bachelor and Master in Dental Surgery, as well as Diplomas in Public Health, in Mental Diseases, and in Tropical Medicine

Application for other information may be made to the Registrar, National University of Ireland, Dublin

The Irish Corporations.

THERE are, in the Irish Free State, three licensing bodies other than the Medical Faculties of the universities, and in Dublin, just as in London, there is a Royal College of Physicians of Ireland, a Royal College of Surgeons in Ireland, and an Apothecaries' Hall. In Dublin, as in London and in Edinburgh, the two Colleges have formed an examining Conjoint Board, which is responsible for the recommendation of candidates to the two bodies for their respective licences. The Apothecaries' Hall of Ireland, like the Apothecaries' Society of London, gives its licence separately

THE CONJOINT BOARD IN IRELAND

This body requires of candidates the passage either of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council as well as passing in the Pre-Registration Examinations in Chemistry and Physics and Biology

PROFESSIONAL EXAMINATIONS

There are three professional examinations, the first of which cannot be passed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the

different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognized medical schools at home and abroad. The first examination deals with (a) anatomy, and (b) physiology and histology. The second examination deals with (a) pathology, (b) materia medica, pharmacy, and therapeutics and ophthalmology, and may be taken separately.

Final Examination—This is divided into three divisions, which cannot be completed until at least five years have passed in medical studies other than those for the Pre-Registration Examinations, and five years at least since the beginning of the curriculum. The divisions are (a) medicine, including fevers, mental diseases, and diseases of children, (b) surgery, including operative surgery, (c) midwifery, including diseases of women and newborn children, and the theory and practice of vaccination.

Fees—Preliminary Examination £2 2s. Re-examination £2 2s. Pre-Registration Examination £3 3s. Re-examination in Chemistry, £2 2s. in Physics, £1 1s. First Professional Examination £15 15s. Second, £15 15s. Final, £6 6s. Re-examination fee is £2 2s. for each division.

Diploma in Psychological Medicine

There are two examinations in connexion with this diploma. Part I consists of (a) anatomy and physiology of the nervous system, (b) psychology. Part II—(a) neurology including clinical and pathological neurology, (b) psychological medicine, including its legal relationships.

Fees—£3 3s. for each part.

Further information can be obtained from Mr. Alfred Miller, Secretary of the Committee of Management, Royal College of Surgeons, St. Stephen's Green, Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND ROYAL COLLEGE OF SURGEONS IN IRELAND

The Diploma in Public Health

Every candidate for the Diploma in Public Health must observe the following rules:

Rule 1 A period of not less than two years shall elapse between the attainment by a candidate of a registrable qualification in Medicine, Surgery, and Midwifery and his admission to the Final Examination for a Diploma in Public Health.

Rule 2 The curriculum for the Diploma in Public Health shall extend over a period of not less than twelve calendar months subsequent to the attainment of a registrable qualification.

Rule 3 Every candidate shall produce evidence of having attended during a period of not less than five months at an institution approved by the Licensing Body granting the Diploma in Public Health in—

(a) Bacteriology and Parasitology (including Medical Entomology), especially in their relation to diseases of man and to those of the lower animals.

(b) Chemistry and Physics in relation to Medicine.

(c) Meteorology and Climatology in relation to Medicine.

At least 120 hours must be devoted to the study of these subjects.

At least 80 hours must be occupied in practical laboratory work.

At least 10 hours must be devoted to Course (c).

Rule 4 Every candidate shall produce evidence of having received during not less than 80 hours at an institution or from teachers approved by the Licensing Body granting the Diploma in Public Health in the following subjects:

(a) The Principles of Public Health and Sanitation (30 hours).

(b) Statistics (20 hours).

(c) Administration (including Public Medical Planning) (10 hours).

[The proportion of time to be given to each subject.]

Rule 5 Every candidate shall produce evidence that he has attended for three months on the clinical practice of a recognized Hospital for Infectious Diseases and has received therein instruction in the methods of administration. At least thirty daily attendances of not less than two hours in each week shall be required.

Rule 6 Every candidate shall produce evidence that he has during a period of not less than six months been engaged in requiring a practical knowledge of the duties routine and special of Public Health Administration under the supervision of a Medical Officer of Health who shall certify that the candidate has received from this Officer or other competent Medical Officer during not less than three hours on each of six working days practical instruction in the duties and also those relating to—

(a) Maternity and Child Welfare Service.

(b) Health Service for Children of School Age.

(c) Venereal Diseases Service.

(d) Tuberculosis Service.

(e) Industrial Hygiene.

(f) Infection and Control of Food including meat and milk.

Candidates of having received the prescribed instruction in Public Health Administration must be given by a Medical Officer of Health who devotes his whole time to Public Health work or by the Medical Officer of Health of a Sanitary Area having a population of not less than 50,000 or in Ireland the Medical Superintendent Officer of Health of a County or County Borough having a population of not less than 50,000.

Part I The examination for the Diploma shall be divided into two parts: Part I and Part II.

Part I The examination for Part I shall include the following subjects:

Bacteriology and Parasitology (including Medical Entomology), Chemistry and Physics in relation to Medicine, and Meteorology and Climatology in relation to Medicine.

Part II The examination for Part II shall include the following subjects:

Hygiene and Sanitation (including Sanitary Canon Law), Epidemiology and Infections in the Community, Sanitary Law and Vital Statistics, Public Health Administration.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

The examination shall be written and oral and shall include practical examination in Infectious Diseases, Food Inspection, Inspection of premises—dairies, factories, workshop, schools, etc.

MEDICAL SCHOOLS AND COLLEGES.

LONDON

Information as to the fees at each of the various metropolitan medical schools, and the scholarships, prizes, and junior appointments which they offer, will be found in the following pages. The courses they provide are fundamentally the same, and in all of them the arrangements made are such as to meet the requirements of students of every class—of those who are aiming at the diplomas of the English Conjoint Board or the Apothecaries' Society, not less than of those who have London or other university degrees in view. At all, too, special facilities are offered to students who have commenced their professional education at Oxford or Cambridge, and are seeking the medical degrees of those universities.

CHARING CROSS HOSPITAL

This school, with its hospital, is situated in the centre of London, and is easily accessible. Primary and intermediate students attend lectures and practical work at King's College. The final studies are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for the qualifying examinations. Departments are also available for the other final subjects of bacteriology, clinical pathology, biochemistry, materia medica, public health, operative surgery, and for research work. An Institute of Pathology, with a whole-time staff of scientific workers and fully equipped laboratories, has been established in the school. Students receive their training in preventive medicine, pathology, and bacteriology here, and are encouraged to undertake research.

Women students are admitted to the school and hospital upon the same terms and conditions as men, and after qualification are eligible for resident hospital appointments.

Fees—The fees are as follows—Entrance Primary and Intermediate 10 guineas Final 8 guineas Annual £42.

Further information may be obtained on application to the Dean of the Medical School, Charing Cross Hospital, London, W C 2.

Guy's Hospital

The hospital contains 616 beds in constant occupation. Twenty-six beds are set apart for diseases of the eye, and 40 for the most urgent and interesting medical cases, which form the subjects of the weekly clinical lectures. There is a special ward of 32 beds for the reception of cases of diseases of women and for cases of difficult labour. Beds are also allotted to the throat and ear departments, the departments of orthopaedics, neurology, and dermatology, the department for the treatment of diseases of the genito-urinary system, and the children's department; there are also some special beds for the treatment of syphilis.

The residential college fronts the east gate of the hospital, providing accommodation for resident students. This contains a dining hall, reading rooms, a library of general literature, and a gymnasium for the use of the residents and of the members of the Clubs Union. The athletic ground at Honor Oak Park is reached from the hospital in twenty minutes. The Gordon Museum of Pathology, the Wills Library, the departments of chemistry, physics, pathology, and pharmacology, and the school buildings in general, afford opportunities for a liberal education and for research, and provide the full curriculum for a medical qualification. New departments of anatomy, physics, and biology were opened in July, 1923. They are equipped on modern lines, and provide ample accommodation for teaching and research. Special classes are held for the First and Second Examinations for medical degrees of the University of London, for the Pre-Medical Examination, and for the First and Final F.R.C.S. Eng. Special teaching is provided to meet the requirements of the Universities of London, Oxford, and Cambridge in general pathology and pharmacology.

Appointments—All appointments are made according to the merits of the candidates, as determined by a committee of the medical staff. Sixteen out-patient officers, eight house-physicians, twenty assistant house surgeons, eight house surgeons, four ophthalmic house surgeons, two genito-

urinary house-surgeons, two house-physicians (children's department), and nine resident obstetric assistants are appointed annually. The house-physicians and house-surgeons, obstetric residents, ophthalmic house surgeons, and genito-urinary house surgeons hold office for six months each, and receive free board and lodging in the college. Every student is provided with rooms and commons in the hospital during the period of his "take in" as senior dresser. In addition to the clerkships and dresserships in the medical and surgical wards, students are appointed to the posts of clinical assistant, dresser, or clerk in the special departments of ophthalmology, laryngology, gynaecology, diseases of children, diseases of the nervous system, dermatology, otology, radiotherapeutics, anaesthetics, dentistry, orthopaedics, vaccine, tuberculosis, fractures, and genito-urinary and venereal disease, clinical assistantships in the various special departments are open to post-graduates.

Scholarships Prizes etc—The following scholarships in Arts and Science are awarded. A Open Junior Scholarships (1) An Arts Scholarship of the value of £100 (2) A Science Scholarship of the value of £100 these are awarded annually in July. (3) A War Memorial Scholarship of the value of £200 awarded alternately in Arts and Science. This Scholarship is open every other year the next award will be made in July 1926. B Confined Scholarship in Science. A Junior Science Scholarship of the value of £100 is offered for competition annually in September to candidates who have attended the preliminary science classes at this school. Candidates for these scholarships (male students only) must be under 21 years of age on October 1st of the year of the competition. C Open Senior Science Scholarships (1) A War Memorial Scholarship of the value of £200, (2) an Open Scholarship of the value of £200 both of these are awarded annually in September. Full particulars as to the scholarships may be obtained from the Dean of the Medical School. Junior prizes for general proficiency £20 £15 £10 Hilton prize for Dissection, £5 Michael Harris prize for Anatomy £10 Sands Cox Scholarship for Physiology, £15 for three years Woodbridge Memorial prize for Physiology £10 Beane prize for Pathology £34 Treasurers gold medal in Medicine Treasurers gold medal in Surgery and the Golding Bud gold medal and scholarship for Bacteriology (£20) are awarded annually after competitive examination. The Cull Studentship in Pathology of the value of £250 per annum, the Berney Scholarship in Materia Medica, of the annual value of about £50 and the Anderson Demonstratorship in Clinical Chemistry value £150 per annum are awarded without examination to enable research to be carried on in these subjects. An Arthur Durham Travelling Scholarship of £100 is awarded triennially. The Griffiths Demonstratorship in Pathology of the value of £320 per annum, and the Hilda and Ronald Poulton Fellowship value £150 per annum, are awarded without examination.

An annual composition fee is paid by all students until a registrable qualification is obtained. Further information may be obtained from the Dean of the Medical School, Guy's Hospital, London Bridge, S E 1.

King's College Hospital

The medical school of this hospital, which is situated at Denmark Hill, deals with the advanced or final subjects of the medical curriculum. The hospital was opened in 1913, and is one of the most modern and best equipped in England. The number of attendances in the casualty and out-patient departments during the year 1924 amounted to 196,211. In the education at the hospital a special feature has always been the individual attention given to each student. The studies are co-ordinated under the direction of senior members of the honorary staff, assisted by medical, surgical, obstetric, and pathological tutors. There are special departments for diseases of women and children, nervous diseases, ophthalmology, otology, laryngology and rhinology, dermatology, radiology, and physiotherapy. The laboratory and pathological department are specially noteworthy.

Appointments—Sixteen resident medical and surgical officers are appointed half-yearly, as well as dressers and clerks in the wards, out-patient departments, *post mortem* rooms, and special departments. Each of the special departments has several clinical assistants. There are three registrars and four tutors, all of whom receive salaries. The Clubs and Societies Union combines athletics, music, and other societies connected with the school, and provides also a common room.

Scholarships etc—At entrance Science Scholarship £50. At commencement of Final Studies Anatomy and Physiology Scholarship £50. Pathology and Pharmacology Scholarship £50. Two Raymond Gooch Scholarships each £50 a year for two years. Two Burney Yeo Scholarships each £80 (for Oxford and Cambridge students). Epsom College Scholarship £50. Senior Scholarship, £40, Todd Prize, Tanner Prize, Class Prizes and Medals.

Fees—The composition fee is 93 guineas if paid in one sum. Entrance fee of 10 guineas includes membership of the Clubs and Societies Union.

New Dental School—This school was opened in October, 1923, and provides complete courses for dental degrees and diplomas. The director of dental studies is Dr. A. Livingston, M.B., Ch.B., M.D.S. Liverpool.

The extension of the school can be obtained on application to the Dean H. Willoughby Lytle, M.D., F.R.C.S., or to the Secretary of the Medical School, S. C. Rammer, M.A., King's College Hospital, Denmark Hill, S.E.5.

THE LONDON HOSPITAL

This hospital, with its medical college and dental school, is situated in the Mile End Road, L.1. The hospital contains 950 beds, and during 1924, 17,975 patients passed through the wards and 131,969 out-patients received treatment. Of the latter number, 37,934 received treatment in the departments for diseases of the ear, nose, throat, eye, skin, and teeth, and in the pediatric, orthopaedic, venereal, radiological, electric, and physiotherapeutic, and inoculation departments. The number of major operations which were performed amounted to 7,656.

The hospital presents, therefore, a large field for clinical instruction, and in its wards and out-patient and special departments exceptional opportunities are afforded for acquiring an extensive and practical experience of all phases of disease.

A clinical unit in medicine, under the charge of a whole-time director, provides for the more advanced methods of diagnosis and treatment, and takes a leading part in the initiation and co-ordination of medical research. To each medical and surgical firm throughout the hospital there is attached a first assistant, who is responsible for instructing the clerks or dressers of the firm in elementary medicine and surgery, and who assists the honorary members of the firm in the preparation of their demonstrations. Special courses of lectures and demonstrations are arranged in medicine and surgery and in their ancillary subjects. Opportunities for research are provided under the supervision of the staff.

All the departments are modern and adapted for the teaching of all subjects in the various curricula. Special courses of instruction are held in preparation for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, and for the Membership of the Royal College of Physicians. Special entries can be made for the medical and surgical practice of the hospital. A residential hostel on hospital ground is provided for the convenience of students who wish to live near the wards and casualty departments. The athletic ground, of over thirteen acres, is at Highams Park, and is open to all members of the Clubs Union.

Appointments—The salaried appointments open to past students of the hospital are those of assistants to the medical unit, first assistants to the medical and surgical firms, obstetric registrar, medical, surgical, and obstetric tutors, clinical assistants in the medical, surgical, ophthalmic, aurial, light and skin, orthopaedic, and electrical departments, and in the Pathological Institute. There are appointed annually 4 resident accoucheurs, 14 resident house-physicians and 22 resident house-surgeons, 14 resident receiving-room officers, 8 resident emergency officers, 8 clinical assistants to the medical out-patient department, and 16 clinical assistants to the surgical out-patient department, also paid and unpaid clinical assistants in the various special departments. In addition, there are numerous assistantships, clerkships and dresserships in the departments of medicine, surgery, gynaecology, and obstetrics.

Scholarships and Prizes—The following is a list of scholarships and prizes.—At Entrance: Price Scholarship in Science £100; Price Scholar in Physiology, open to students of Oxford and Cambridge £75; Entrance Scholarship in Science £75; Free Medical Education. After Entrance: Buxton Prize in Anatomy and Physiology £40; Letheby Prizes in Organic Chemistry and Chemical Pathology £25; Prizes in Clinical Medicine, Surgery, and Obstetrics and Gynaecology £20 each; Duckworth Nelson Prize in Practical Medicine and Surgery £10; Hutchinson Prize in Clinical Surgery £50; Treves Prize in Clinical Surgery £15; Sutton Prize in Pathology £20; K. E. D. Payne Prize in Pathology £20; Sir Andrew Clark Prize in Clinical Medicine and Pathology £25; Anderson Prizes in Elementary Clinical Medicine £20; Dressers Prizes £40; Practical Anatomy Prizes, £10; Arnold Thompson Prize in Medical

and Surgical Diseases of Children £15; Liddle Prize £120; Francis Turner Scholarship in Dental Surgery £25; Harold Fink Prize in Dental Surgery £8; The London Prize in Dental Surgery and Pathology £5 5s.; and in Dental Practice £5 5s. Seven clinical examination prizes, each of the value of £3 3s., are offered for competition at the end of the courses of lecture in the dental curricula. Funds to the value of approximately £4,000 per annum for financial assistance being given to students and graduates engaged in medical research.

Fees—Entrance fee 20 or 15 guineas, according to examination; passed annual fee 40 guineas.

Full information may be obtained from the Dean at the London Hospital Medical College, Mile End, L.1.

THE MIDDLESEX HOSPITAL

This school and hospital are in Mortimer Street, W.1, close to Oxford Circus, Coombe Street, and Great Portland Street stations. There are a gymnasium, common room, and restaurant within the hospital precincts, and an athletic ground within easy reach. The hospital contains over 450 beds, including a wing containing 92 beds for patients suffering from cancer. There are special wards for maternity and gynaecological cases, for mental cases, for cases of venereal disease, and for diseases of children and of the skin and eye.

The medical school, which includes the Bland Sutton Institute of Pathology and the cancer research laboratories, is completely equipped for teaching the entire medical curriculum, including the pre-medical subjects chemistry, physics, and biology. The Bland Sutton Institute, under the charge of the Professor of Pathology, contains large pathological and public health laboratories, a separate department of biochemistry, and smaller rooms for original investigation as well as a pathological and anatomical museum. Bacteriological, chemical, and microscopical examinations of material from the wards, operating theatres, and out-patient departments are carried out in the laboratories, and senior students are eligible for clerkships in connexion with this work. Junior students in the pathological and bacteriological laboratories are elected annually from recently qualified students. Every facility is given for original research. The cancer research laboratories offer unlimited opportunities for the study of this disease, in both its clinical and pathological aspects.

Appointments—Twenty-two resident appointments are open annually for competition among students of the hospital. The officers reside and board in the residential college free of expense. Two casualty medical and two casualty surgical officers, and two resident officers to the special departments, are appointed annually. Eight house-surgeons are appointed every year at intervals of two months, after examination, six house-physicians are also appointed annually at similar intervals. An obstetric and gynaecological house-surgeon is appointed every six months. Eight registrars are appointed annually. In the out-patient departments the appointments are clerk and dresser to the physicians and surgeons to out-patients; clerk in the departments for diseases of the skin and nervous diseases, dressers to the department for diseases of women, to the ophthalmic surgeon, to the throat and ear department, and to the dental surgeon. External midwives, clerks and post-mortem clerks are also appointed. The appointments are so arranged that every student may, during his course, hold all the out-patient and in-patient clerkships and dresserships. Students must have held an out-patient clerkship and dressership before holding in-patient clerkships or dresserships. Non-resident qualified clinical assistants are appointed in the medical, surgical, skin, neurological, ophthalmic, throat and ear, odontological, children's, and electrotherapeutic out-patient departments.

Scholarships—There are two Entrance Scholarships, value £100 each. Two annual Entrance Scholarships of the value of £90 and £60 respectively are open to students of the University of Oxford and Cambridge who have completed the curriculum for, or passed the examinations in anatomy and physiology. Students joining the school in the previous April are eligible. The Peter Lucas Scholarship is annually awarded on the nomination of the headmaster to a pupil of Epsom College who has passed the first examination for medical degrees (Preliminary Scientific Examination). There is also a scholarship, value £50, awarded annually to students from New Zealand. In addition to the Entrance Scholarships there are numerous other valuable scholarships, prizes and exhibitions open to students of the hospital, including the Brodrip Scholarships, value £60 and £40; Lyell Gold Medal and Scholarship, value £55 5s.; Freeman Scholarship, value £30; John Murray

Gold Medal and Scholarship value £25, Hatley Clinical Prize, value £25, Leopold Hudson Prize value 11 guineas, and the Second Year's Exhibition, value 10 guineas.

Fees—(a) Pre-medical students for one year or less £21 (b) Students who have completed the Preliminary Science course Entrance fee 25 guineas five annual fees of £45. The annual fee for further attendance at the medical school, if a registrable qualification has not been obtained, is £23. Three quarters one half of one-quarter of the last annual fee may at the discretion of the School Council be returned if the student obtains a registrable qualification within three, six, or nine months of the annual payment becoming due. (c) Oxford and Cambridge and other students who have completed the Intermediate course Entrance fee 15 guineas two annual fees of £45 further annual fees as above. These fees are inclusive and cover the cost of instruction in vaccination fevers etc. and also the subscription to the amalgamated clubs and hospital Journal.

Further information may be obtained from the Dean or the School Secretary.

ST BARTHOLOMEW'S HOSPITAL

This institution fills one side of Smithfield and Giltspur Street, covering the greater part of a large island of ground separated practically from all other buildings, it is on the edge of the City, and easily reached from all parts of London. The hospital contains 757 beds. Extensive buildings, opened in July, 1907, occupy part of the ground acquired from the old Bluecoat School, and these materially enhance the attractions of the hospital as a place of medical study. The medical school buildings, including the library, the museum, and the chemical, biological, and anatomical departments, have now at their side a very large building, which includes club rooms for the Students' Union, a writing room, luncheon and dining halls, new quarters for the resident staff, and an out-patient department and accommodation for special departments of such large size as to be unsurpassed by any hospital in the kingdom. During the year 1909 a second block of new buildings was completed. These form the pathological department, and include, in addition to an extensive *post-mortem* room, large and well equipped laboratories for clinical pathology, pathological histology, bacteriology, and chemical pathology, altogether forming the most complete pathological department in the country. A further large block in Giltspur Street was required in 1923, and has been equipped by the construction of new lecture theatres and extensive laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology. Within the precincts of the hospital there is also a residential college for a large number of students. The Students' Union owns grounds of some ten acres in extent for recreative purposes at Vinchmore Hill, which is easily accessible from the hospital.

Special classes are held for students preparing for the Preliminary Scientific and other examinations, for the M.B. M.D. of the Universities of Oxford Cambridge, and London, and for the higher surgical degrees at the same universities, including the M.Ch. Oxon., M.Ch. Cantab., M.S. Lond. and F.R.C.S. Eng.

Clinical Units—Special clinical units have been established in medicine and surgery, each under the charge of a professor and director who devotes the whole of his time to the purpose of hospital practice teaching, and research. In each unit there are in assistant director and four assistants, for whom special laboratory accommodation has been provided by a gift from the Sir William Dunn Trustees. The appointments of clerks and dressers are open to all students in these departments and arrangements are made for all students to study in these units during a part of their clinical course.

Appointments—Clinical clerks to the physicians and to the physio-therapists, and dressers to the surgeons and in the casualty department, are chosen from the students, clerks and dressers are also selected from the students to attend in the out-patient rooms, in the special departments (ophthalmic, orthopaedic, gynaecological children's, laryngological, rural, dermatological venereal, electrical, and dental), and in the *post-mortem* room. Chief assistants and clinical assistants are selected from qualified men appointed yearly to help in the general medical surgical, and in the special departments. Ten house-physicians and ten house-surgeons are appointed annually. During their first six months of office they act as 'junior' house-physicians and house-surgeons and receive a salary of £80

a year. During their second six months they become 'senior' house-physicians and house-surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house surgeon, a house surgeon to the skin and venereal department, and a house surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Three resident administrators of anaesthetics are appointed—the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum—and all are provided with board and rooms. An external midwifery assistant is appointed every three months, and receives a salary of £80 a year.

Scholarships—Four entrance Scholarships are annually awarded after examinations held in September. The subjects of examination and conditions of eligibility for these scholarships are: (1) One scholarship value £75 in not fewer than two and not more than three of the following subjects—chemistry physics botany zoology physiology and anatomy limited to students under 25 years of age who have not entered on the medical or surgical practice of any London medical school. (2) One scholarship, value £100, in not fewer than three of the following subjects—chemistry physics botany zoology, and physiology limited to students under 21 years of age who have not entered on the medical or surgical practice of any London medical school. (3) An entrance scholarship in arts of the value of £100 in Latin and mathematics with one other language—Greek French or German. (4) The Jefferson Exhibition in Mathematics Latin and one other language—Greek, French or German—of the value of £50. The total value of the scholarships and prizes is over £1,000 annually.

Further information and a handbook can be obtained on application to the Dean of the Medical College, St Bartholomew's Hospital EC1.

ST GEORGE'S HOSPITAL

This school is at Hyde Park Corner, and is carried on in connexion with St George's Hospital, an institution having a service of 436 beds, of which 100 are at the convalescent hospital at Wimbledon. It provides for the instruction of its students in the preliminary and intermediate subjects of the curriculum at the teaching centre of London University established at King's College. The school at Hyde Park Corner is devoted entirely to the teaching of clinical subjects, great attention being paid by the members of the staff to individual teaching. A number of special courses are given, in which the requirements of university and all other examinations receive careful attention.

The St George's Hospital Club consists of an amalgamation club, with smoking and luncheon rooms on the hospital premises, and other students' clubs, with an athletic ground at Wimbledon. Students have the advantage of a well filled library of medical and scientific books. A register of accredited apartments and a list of medical men and others willing to receive St George's men as boarders may be seen on application to the Dean.

Appointments—Two house-physicians, two house-surgeons, and two casualty officers are appointed every two months. The house officers reside and board in the hospital free of expense. The casualty officers are non-resident, and receive salaries at the rate of £100 per annum. After the student has held a house appointment, the following are, among others, open to him: assistant resident physician at £350 per annum, assistant resident surgeon at £350 per annum, medical officer to the Atkinson Morley Convalescent Hospital at £300 per annum, medical registrarship at £200 per annum, surgical registrarship at £200 per annum, medical officer to the biochemical department at £100 per annum, assistant curatorship of the museum, £100 per annum, obstetric assistantship resident, at £50 per annum, the post of resident anaesthetist at £100 per annum, the posts (two) of junior anaesthetist, each at £30 per annum.

Scholarships—The following Entrance Scholarships and Exhibitions in anatomy and physiology are awarded in July to candidates who have passed the second M.B. London or corresponding examination. Senior William Brown Exhibition of the value of £150. Senior Scholarship of the value of 90 guineas. Junior William Brown Exhibition of the value of £60. Junior Scholarship of the value of £70. Devitt Pendlebury Scholarship of the value of £50. and Exhibitions each of the value of £40 and up to six in number. Other prizes to the value of £200 are awarded annually to the students of the hospital.

Fees—First year (First M.B. or pre-medical course) £36 15s. second and third years £12 each. For the course of clinical

study in the fourth and subsequent years, entrance fee £10 10 annual composition fee £42. No entrance fee is payable by St George's students who have studied at King's College. Further information may be obtained from the Dean of the Medical School.

ST MARY'S HOSPITAL

This hospital and medical school are situated close to Paddington Station (G W R), having on one side a poor district of 500,000 persons, and on the other side the residential district of Kensington and Bayswater. The hospital contains 288 beds, and, by a scheme of affiliation, for teaching purposes, of several neighbouring hospitals, the teaching facilities extend over 1,000 beds. By arrangement with the Lock Hospital, students take the courses of instruction in venereal diseases there. The athletic ground (ten acres) is situated at Wembley, and can be reached in twenty minutes by a constant service of trains, a large pavilion has recently been erected.

Clinical Facilities.—Clinical units in medicine and surgery were established in 1920, and have now been formally recognized by the University Grants Committee, St Mary's being one of the six medical schools in London which enjoy this privilege. In addition to the lying-in beds at St Mary's, every student attends a short course at Queen Charlotte's Maternity Hospital (which is situated near to St Mary's) before holding a post on the maternity district of the hospital.

Institute of Pathology and Research.—Students specially interested in pathology and bacteriology have singular advantages at St Mary's. The Institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright, F.R.S. Research scholarships of £200 each are awarded annually to students working in the departments of the Institute, and research beds are provided. Clerkships in pathology and bacteriology and chemical pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the pathological and bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually.

Complete Curriculum.—The medical school provides complete courses of instruction, and students can join at once on passing a Preliminary Examination in Arts. Terms begin in October, January, and April.

Entrance Scholarships.—Three entrance scholarships of £210 each and one of £26 5s. are awarded annually in July by nomination on the lines of the Rhodes Scholarships. Two University Scholarships of £200 are awarded annually in July.

Fees.—Composition fees for entire curriculum (5½ years) £200 in one sum or £210 by five annual instalments. Composition fee for clinical curriculum (2½ years), 90 guineas in one sum, or 95 guineas by two annual instalments. As an alternative students may pay an annual fee of 40 guineas with an entrance fee of 10 guineas.

ST THOMAS'S HOSPITAL

This school and hospital are situated in Lambeth, on the south bank of the Thames, facing the Houses of Parliament, and form one of the well known architectural features of London.

The school buildings, which are separated from the hospital by a quadrangle, comprise lecture theatres, laboratories, and classrooms well adapted for the modern teaching of large bodies of students in the subjects of the medical curriculum. A splendid library and reading room and a complete museum are open to all students from 9 a.m. to 5 p.m., on Saturdays to 1 p.m. The Students' Club premises contain a dining room and smoking and reading room supplied with daily and illustrated weekly papers, and a gymnasium. Good meals are obtainable at a moderate tariff. The terrace affords facilities for exercise and recreation. The sports ground, of more than nine acres in extent, is at Chiswick. It can be reached in forty minutes from the hospital, it is admirably adapted for football, cricket, lawn tennis, and athletic sports.

The hospital proper contains 644 beds. In addition to the ordinary provisions of a great hospital there are connected with the out-patient department physicians' and surgeons' rooms provided with ample sitting accommodation, so that students are enabled to follow closely the practice and

teaching of the out-patient staff. There is a full complement of special departments, and connected with the hospital a special tuberculosis department gives opportunity for instruction of students. There is a clinical theatre centrally situated, so as to facilitate the illustration of lectures by patients from the wards, and out-patient room. It is arranged also for lantern demonstrations. The maternity ward, containing 20 beds, gives students full facilities for maternity training under supervision, within the precincts of the hospital. This obviates any need for supplementary instruction elsewhere, and fully prepares the student for the external maternity practice of the hospital district. The revised regulations of the examining bodies can thus be fully complied with.

Appointments.—All hospital appointments are open to students without charge. A resident assistant physician, a resident assistant surgeon, and a resident anaesthetist are appointed annually at a salary of £200 each per annum. Two hospital registrars, medical and surgical, at an annual salary of £250 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. An obstetric tutor and registrar, an ophthalmic registrar (at an annual salary of £50 each) and an orthopaedic registrar (impud.) are appointed yearly. Ten resident casualty officers and anaesthetists (including two seniors) are appointed every six months. Seven house-physicians (including two obstetric house-physicians and one house-physician to the department of diseases of children) and nine house-surgeons (including two ophthalmic house-surgeons, one orthopaedic house-surgeon, and two house-surgeons to the ear, nose, and throat department) are appointed every six months. Eight or more clinical assistants in the special departments are appointed every three months, and hold office for six months if recommended for re-election. Clinical clerkships and dresserships to the in-patient and out-patient departments are available to the number of 400 each year.

Scholarships.—There are five entrance Scholarships. Two in art giving one year's free tuition, one of £150 and one of £20, in chemistry, physics and biology for students who have not received instruction in anatomy or physiology, one of £100 in any two of the following subjects: anatomy, physiology or chemistry for students who have completed their examinations in anatomy and physiology for a medical degree in any of the universities of the United Kingdom or the Colonies and have not entered as clinical students in any London medical school. The money value and subjects of examination of the remainder are as follows: (a) William Tite Scholarship for second year students £25. (b) and (c) Musgrave Scholarship or (alternately) Peacock Scholarship each for third year students and tenable for two years £35 each. (d) Mead Medal Medicine, Pathology and Hygiene. (e) Wainwright Prize Medicine, Pathology and Hygiene. (f) Toller Prize Medicine. (g) Cheselden Medal, Surgery and Anatomy. (h) Clutton Memorial Medal in Clinical Surgery, biennial. (i) Beaver Scholarship £50 biennially. Surgery and Surgical Pathology. (j) Soler Medal and Prize biennially. Reports of Cases. (k) Sutton Sam Prize, biennially. Reports of Cases. (l) Bristowe Medal, Pathology and Morbid Anatomy. (m) Hadden Prize Pathology. (n) Grainger Testimonial Prize £31 10. Anatomy and Physiology. (o) Louis Jenner Research Scholarship tenable for two years, £60 annually, Pathology.

Fees.—The annual fees are £50. These fees cover all tutorial classes, but do not include instruction in infectious fevers, pharmacy and vaccination. Qualified practitioners are permitted to attend the hospital practice on terms which may be ascertained from the Medical Secretary.

Special courses of instruction are given for various examination, and a register of lodgings is kept at the school. Further information may be obtained from the Medical Secretary of the School. St Thomas's Hospital, Albert Embankment SE1.

UNIVERSITY COLLEGE HOSPITAL

The school, which forms part of the Corporation of the University College Hospital, is in immediate proximity to the hospital in University Street, and opposite University College. It comprises departments of medicine and clinical medicine, surgery and clinical surgery, midwifery and gynaecology, pathology including morbid anatomy, chemical pathology, biochemistry and bacteriology, cardiography, forensic medicine, mental physiology and mental diseases, dental surgery, practical pharmacy, and other departments for the study of special diseases, such as those of the eye, skin, ear and throat, venereal diseases, and for instruction in anaesthetics, electrotherapeutics, and skiagraphy. The Hospital and School have acquired the National Dental Hospital and College as their dental departments thus

providing every facility for the study of dental subjects. The Royal Free Hospital, Dean Street, Soho, has also been incorporated as the Ear, Nose, and Throat Department.

The school thus provides the final course of study for the lectures of the Universities of Oxford, Cambridge, London, Durham and other British universities, and for the diplomas of the Royal Colleges of Physicians and Surgeons in Medicine and Dental Surgery, and the Licence of the Society of Apothecaries. Special bacteriological classes are also held in preparation for the various diplomas in public health. Each department is also equipped for more advanced work, and provides facilities for research.

Clinical units in medicine and surgery are now in operation. The whole-time directors of the units are concerned with the organization of the teaching generally, but the honorary staff is responsible for the largest share of the teaching in the wards and out-patient department of the hospital. A unit in obstetric medicine will be established as soon as the new obstetric hospital now in course of construction is finished.

The new buildings of the obstetric hospital of 60 beds (rendered possible by the Rockefeller benefaction), the new Residents' House (with accommodation for 30 residents and students), the extension of the Nurses' Home, and the new research laboratories for the Medical School, are well under way and these buildings should be ready for occupation by the end of the year.

Appointments—The qualified appointments in addition to a number of posts as house-physicians and house surgeons and obstetric assistants, include the appointments of resident medical officer, medical registrar, surgical registrar, obstetric registrar, Harter Smith radium registrar, casualty medical officers, casualty surgical officers, assistants in ear, nose and throat, ophthalmic skin and venereal diseases departments, and house anaesthetists.

Scholarships—The following scholarships and prizes are open to competition. Two Entrance Exhibitions of 112 guineas each awarded after a competitive examination in anatomy and physiology. Radcliffe Crocker Travelling Scholarship in dermatology for one year value about £280. The Graham scholarship in pathology of a sum not exceeding £100 per annum. Leslie Pearce Gould Research Scholarship in surgery for one year value about £200. The Atkinson Marley Scholarship of £45 a year for three years awarded after examination in the theory and practice of surgery. The Anderson Scholarship of £55 a year for two years for general proficiency in medical studies. The McGrath Clinical Scholarship value about £100. The Jilster Exhibition in pathology of £50. The Perci Allern Prize for the advancement of surgery by research value about £60. The Graham Gold Medal for research work. Four Fellows Medals in clinical medicine. Liston Medals in clinical surgery. The Bruce Medal in pathology and surgery. Two Tulke Medals in pathology. and the Druehlen Prize for practical surgery.

Fees—The fee for the full course of final studies at the school is 112 guineas if paid in one sum or 115 guineas if paid in two instalments. Fees for vaccination fevers, and pharmacy not included.

Particulars of general and special courses can be obtained on application to the Dean of the Medical School, University College Hospital, University Street, W.C.1.

WESTMINSTER HOSPITAL

This school with its hospital, situated in Broad Sanctuary, opposite Westminster Abbey, provides for the education of its students in the preliminary and intermediate subjects of the University of London at King's College. The rest of the work is done in the school buildings near the hospital. The number of in-patients averages 3,000 and out-patients upwards of 50,000 annually, and the hospital and school afford ample facilities for instruction in all branches of medicine and surgery.

Appointments—A medical and surgical registrar are appointed annually, each with a salary of £150 and obstetric registrar with a salary of £50. Three house-physicians, three house-surgeons, one assistant house-physician, one assistant house-surgeon, and a resident obstetric assistant are appointed after examination and are provided with rooms, commons, and salary of £52 per annum, except the assistant house-physician and the assistant house-surgeon, who are provided with commons only. The assistant house-physician after three months' service becomes house-physician for a further period of six months and the assistant house-surgeon after three months' service becomes house-surgeon for a further period of six months. Clinical assistants to the resident phy-

sicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among the qualified students. Every student must perform the duty of out-patient dresser for three months, and afterwards he is appointed as in-patient dresser for three months. He is also required to serve two terms of three months each as medical clerk to the in-patient physician and one term as gynaecological clinical clerk. Two pathological clerks are appointed every three months to assist in the post-mortem room. No student is eligible as an in-patient dresser or clinical clerk until he has passed the Second Examination of the Conjoint Board, or an equivalent examination. Clerks and dressers in the special departments of hospital practice are periodically appointed. So far as vacancies permit, students of other hospitals are admitted to in-patients' dresserships or clerkships.

The governors of the hospital have now completed the extensive improvements and alterations to the hospital which render it a still more efficient teaching institution with an increased number of beds.

Scholarships—The following open scholarships are offered for competition during the year 1925-26. In the winter session two scholarships in anatomy and physiology £70 each. In the spring two scholarships in anatomy and physiology £70 each. A certain number of scholarships have been allotted to universities of England, Wales, and the Colonies and to public schools. The scholarships are awarded entirely on the nomination of the Principal of the university or school.

Fees—The annual composition fee is 35 guineas. An entrance fee of 10 guineas is payable by all students—namely primary and intermediate students £10 10s. students entering for the first subjects £8 8s. These fees include subscriptions for membership of the Clubs Union.

Further information and a prospectus can be obtained on application to the Dean at the Westminster Hospital, Westminster, S.W.1.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN

The school is situated at 8, Hunter Street, Brunswick Square, W.C.1, close to the Royal Free Hospital. It is like all the other London schools which have so far been mentioned, one of the constituent schools of London University. The school buildings have recently been enlarged. The laboratories are extensive and well lighted, and are fully equipped for the examination courses of the University of London and the Royal Colleges of Physicians and Surgeons. Research laboratories are attached to all departments. A large, well equipped library, common room, union room and refectory are provided for the use of students. Resident accommodation for 60 students is provided in students' chambers attached to the school.

The Royal Free Hospital, Gray's Inn Road, W.C.1, has 240 beds, all of which are available for clinical instruction. A new block contains the obstetrical and gynaecological unit, which controls 68 beds. A large maternity district is served from the unit with a separate maternity hostel in the Essex Road, Islington. There are separate departments for diseases of the eye, ear, and skin, infant welfare, venereal diseases, massage, electrical and x-ray work, dentistry and casualty. The instruction given covers the full curriculum for the M.B. B.S. degrees of the University of London, including first medical courses. Students attend the practice of one of the fever hospitals of the Metropolitan Asylums Board and receive special instruction in January at Bethlem Hospital, they are also admitted to the practice of a number of special hospitals and hold clerkships and dresserships at the Elizabeth Garrett Anderson Hospital, the Cancer Hospital, Hospital for Sick Children, the National Hospital for Nervous Diseases, the South London Hospital, and the Royal Ophthalmic Hospital. The work of the school includes preparation for the Primary Fellowship examination and also for the Medical School and general hospital course for dental students.

Appointments—Qualified students of the school can obtain appointments as house-physicians and house-surgeons, obstetric assistants, surgical, gynaecological, and medical registrars, assistant pathologists, assistant anaesthetists, medical electrician, sphygmograph, and clinical assistants and demonstrators in various subjects.

Scholarships—The Isabel Thorne Entrance Scholarship value £50. The St. Dunstan's Medical Exhibition value £50 a year for three years which may be extended to five years, the Anne

Langton Scholarship of £50 a year for two years, the Flora Murray Bursary of £50, and the Mabel Sharran Crawford Scholarship value £20 a year for four years are offered for competition in each year. The Sir Owen Roberts Memorial Scholarship of the value of £75 a year for four years—the Mrs. George M. Smith Scholarship of the value of £50 a year for three years, which may be extended to five years—the Dr. Margaret Todd Scholarship of the value of £37 10 a year for four years and the Sarah Holborn Scholarship of the value of £20 a year for three years, which may be extended to five years, are awarded in alternate years. The School Jubilee Bursary of £50 a year or three years is offered every third year. The Bostock Scholarship value £90 a year for two or four years is awarded by the Reid Trustees on the result of an examination held in May by the University of London every fourth year. The holder of the scholarship must enter the London School of Medicine for Women. The Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship of the value of £25 a year for four years is awarded every fourth year. The John Byron Bursary of £20 a year for two years, the Julia Anne Hornblower Cook Prize of £75, the Helen Prideroux Prize of £60, the Mabel Webb Research Scholarship of £30 for two years, the Fanny Butler Scholarship of £14 10 a year for four years together with many other scholarships and prizes are offered on sundry conditions. The Dr. Edith Pechey Phipson Post Graduate Scholarship of £100 is awarded annually. Altogether the School offers annually £1350 in scholarships. Various missionary societies also offer scholarships on certain conditions and assist ladies who wish to go to India and other countries as medical missionaries.

Fees—Courses for the University of London degrees and the diplomas of the Conjoint Board in England and other qualifications £240 payable in five instalments. These sums include library and laboratory fees.

The Students Union exists to promote corporate action of the students on matters of common interest, to promote and maintain athletic and other clubs and to issue a school magazine. All students are required to become members of the Union. The students sports ground which consists of a freehold property of six and a half acres is situated at Sudbury.

Further information can be obtained from the Warden and Secretary.

KING'S COLLEGE

In the Faculty of Medical Science instruction is given in the preliminary and intermediate subjects of the first and second examinations leading to the degree of M.B., B.S. of the University of London, and of the corresponding examinations of other universities, and of the Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons, including the primary examination for the F.R.C.S. Eng. The courses are open to women students on the same terms as to men.

Regular students who have completed their preliminary and intermediate examinations proceed to a hospital to pursue their studies for the final examinations. The hospitals associated with King's College are King's College Hospital, Denmark Hill, S.E.5, Westminster Hospital, S.W.1, St. George's Hospital, Hyde Park Corner, S.W.1, and Charing Cross Hospital, Strand, W.C.2.

A course for the degree of the University of London and for the diploma of the Royal College of Surgeons in dental surgery in conjunction with King's College Hospital Medical School has been arranged. Full details may be obtained on application to the Secretary, King's College Hospital Medical School, Denmark Hill, S.E.5, or to the Dean of the Medical Faculty as below.

Scholarships—The entrance Scholarships are (1) Two Warneford Scholarships each £30 for four years subjects—selected from mathematics, classics, divinity and science. (2) One Sambrook Scholarship of £30 for three years subjects of examination selected from mathematics, classics and science. The holders of the preceding awards must proceed to King's College Hospital. (3) Worsley, £100 paid in five annual instalments. (4) Rabbeth Scholarship value £20, in July, for the best student of the first year. (5) Second year's scholarship value £20 for the best student of the second year. (6) Daniell Scholarship £40 awarded on the results of the University Honours Examination.

Full information as to admission fees and scholarships can be obtained from the Dean of the Faculty of Medical Science (Professor E. Barclay Smith), King's College Strand W.C.2.

UNIVERSITY COLLEGE

This institution, one of the principal component parts of the University of London, possesses a Faculty of Medical Sciences whose work covers all the subjects included in the group commonly known as the preliminary medical sciences—namely, physics, chemistry, botany, and zoology, and also the intermediate medical sciences—namely, anatomy, physiology, and pharmacology. The new anatomy building, provided by the munificent gift of the Rockefeller

Foundation of New York, was opened on May 31st 1923, by His Majesty the King. This building forms part of the block which includes physiology and pharmacology. The department of hygiene and public health prepares for the diplomas in public health of the Royal Colleges and of the various universities. Research work is undertaken in all the above named departments. The College undertakes the education of students in all the subjects mentioned, leaving them free to complete their education in the strictly professional subjects—medicine, surgery, and the like—at any one of the recognized schools of advanced medical studies. The work is somewhat differently arranged, according to whether the student has in view the degrees of the University of London or the diplomas of the Royal Colleges. In either case the whole work to be done is divided into courses devised to meet the requirements of different examinations, and students can join the College for any of them. Women students are admitted to all courses on the same terms as men. The general arrangements for the benefit of students include membership of the Union Society or the Women's Union Society with the College gymnasium and the athletic grounds. There is also a collegiate residence for about fifty-five men students at Laling, and for about seventy women students at Bang Place, Gordon Square.

Scholarships—The scholarships and exhibitions obtainable include the Bucknill Scholarship value 135 guineas, in chemistry, physics, botany, and zoology (the successful student must complete his work at University College Hospital Medical School) and two entrance exhibitions in the same subjects, each of the value of 55 guineas.

Fees—The fees for the courses covering the work of the First Examination for medical degrees of the University of London and in both parts of the Second Examination, amount to 115 guineas. The fees for the courses covering the corresponding examination held by the Conjoint Board in England also amount to 115 guineas. These fees may be divided into payments for the different courses which it may be desired to take out, but do not cover tuition for more than a stated period.

A handbook specially relating to this faculty may be obtained on application to the Secretary of University College, Gower Street, London W.C.1.

THE PROVINCES

There are in England and Wales, not counting London, ten medical schools, each supplying instruction in the full medical curriculum. Accounts of them here follow. In several cases there is appended information about hospitals other than those directly connected with the school in question, such hospitals, officially and unofficially, play a part in the education which the students of the school receive, and in any case serve as places of additional or post-graduate study.

OXFORD AND CAMBRIDGE

At both Oxford and Cambridge there are medical schools which furnish unsurpassed opportunities for obtaining a good knowledge of the preliminary sciences and of anatomy, physiology, and pathology. The laboratories are excellently furnished, and the teaching staffs most distinguished. Both schools provide a full medical curriculum, and there is no essential reason why the student should not complete his career at either of them, but this is not commonly done, and is never in the ordinary way advised by the university medical authorities. The local hospitals, though well equipped, are comparatively small. Students are therefore encouraged, as soon as they have completed the earlier examinations and taken a degree in arts, to join some London school, and thus spend the time of their preparation for the final examinations in a city where the opportunities for gaining clinical knowledge are greater and more varied. A considerable proportion of Oxford and Cambridge medical students take the London Conjoint diplomas before graduating in medicine and surgery at their own university. The experience gained by holding resident hospital appointments is naturally of much advantage when sitting for the Final M.B. examination and when engaged in composing a thesis.

BIRMINGHAM

The school in this city is carried on by the Medical Faculty of the University of Birmingham, its students having an adequate number of good laboratories, classrooms, and other

necessaries devoted to their use by the university. The clinical work is done at the General and Queen's Hospitals, which are amalgamated for this purpose. Together they have upwards of 600 beds for medical, surgical, and special cases, and with an array of special departments of all kinds, including one for lying-in women. Clinical instruction is given in the wards and out-patient and special departments daily, and formal clinical lectures delivered weekly throughout the winter and summer sessions. Special tutorial classes are also held alike for the degrees of Birmingham and some other universities and for the diplomas of corporations.

Appointments—The large number of appointments open to past or other students includes the following—At the General Hospital: surgical registrar, £200 a year, one resident medical officer, salary £155 a year, one resident surgical officer, salary £180 a year, one resident pathologist, salary £70 a year, two visiting anaesthetists, salary £50 a year, four house-surgeons, office tenable for nine months, £70 a year, one house-surgeon to the gynaecological and one to the special departments, each tenable for six months, £70 a year, three house-physicians, post tenable for six months, £70 a year. At the Queen's Hospital: one medical registrar and one surgical registrar, non-resident, tenable for three years, renewable, salary £100 per annum, three house-physicians, three house-surgeons, and one obstetric and ophthalmic house-surgeon, tenable for six months, salary £70 per annum, with board, lodging, and washing, one casualty house-surgeon, tenable for three months, salary £70 per annum, with board, lodging, and washing. At the Maternity Hospital: three house-surgeons, salary £50 a year. At the City Workhouse and Workhouse Infirmary: five resident medical officers. At the Birmingham General and Branch Dispensaries: twelve resident surgeons. At the Birmingham Mental Hospitals: five assistant medical officers. At the City Fever Hospitals: three assistant medical officers. At the Children's Hospital: one resident surgical officer, one resident medical officer. At the Birmingham and Midland Eye Hospital: four resident surgeons. At the Orthopaedic and Spinal Hospital: two clinical assistants (non-resident). At the Ear and Throat Hospital: one house-surgeon, £70 a year, four clinical assistants (non-resident). Four non-resident Poor Law appointments are in the gift of the Board of Guardians.

Scholarships—There are numerous money and other awards for students of sufficient merit among them being the following: The Walter Myers Travelling Studentship of £300 offered each alternate year and tenable abroad (offered in 1925); the Sanders Cox Scholarship of £42 (an entrance scholarship in the Faculty of Medicine awarded on Higher School Certificate Examination of the Joint Matriculation Board (July)); four Queen's Scholarships of £20 10s. each awarded annually at the first (Part II) second, third, and final university examinations respectively; one or more Sydenham Scholarships allotted on entrance to students who are the sons of deceased medical men; the Ingelby Scholarships (two) of £10 for proficiency in midwifery and diseases of women; the Arthur Foxwell Memorial Gold Medal (Clinical Medicine); the Sampson Gamgee Memorial Medal in Surgery (Final M.B.) and the Peter Thompson Prize in Anatomy (value about £6) for students in their second university year. There is also a scholarship of £37 10s. for students proceeding to a degree in dental surgery. University Clinical Board Prizes are awarded annually as follows: Senior Medical Prize, Gold Medal; Senior Surgical Prize, Gold Medal; Midwifery Prize, Gold Medal; Junior Medical Prize, Silver Medal; Junior Surgical Prize, Silver Medal.

Fees—The composition fee for university classes is £106 5s. This covers all the work required for the degrees of Birmingham and some other universities and for the ordinary qualifications of licensing corporations but not the additional courses required for the Fellowship of the Royal College of Surgeons of England, the diploma and degrees of the university in State medicine and some other special work. The total cost for the five years' curriculum including hospital and examination fees is estimated at £193 2s. 6d.

Other information should be sought from the Dean of the Medical Faculty, University, Edmund Street, Birmingham.

BRISTOL

The school is carried on by the Faculty of Medicine of the university, and provides full instruction for all its degrees and diplomas.

Clinical Instruction—The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them about 600 beds and extensive out-patient departments, special clinics for diseases of women and children, and those of the eye, throat, and ear, in addition to large and well equipped departments for dental work and large outdoor

maternity departments. At each of these institutions there are well arranged pathological museum, post-mortem rooms, and laboratories for morbid anatomy. There are also laboratories for work in clinical pathology, bacteriology and extology, in which special instruction is given in the subjects. Departments are provided and well equipped for x-ray work, both for diagnosis and treatment, the various forms of electrical treatment, including high frequency currents, electric baths,insen light treatment, and massage. The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 108 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore about 750.

Appointments—(1) Undergraduate. Clinical clerkships, dresserships, also ophthalmic, obstetric, pathological, ear, nose, and throat clerkships, are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the dressers reside in rotation free of charge. (2) Post-graduate. At the Bristol Royal Infirmary: four house-surgeons, £80 each per annum, two house-physicians, £80, two resident obstetric officers, one of whom is also ophthalmic house-surgeon, £100 and £80, ear, nose, and throat house-surgeon, £80, dental house-surgeon, £80. All these appointments are made for twelve months. From the resident officers a senior resident officer is appointed at a salary of £200. At the Bristol General Hospital: Senior resident medical officer, £250 per annum, casualty house-surgeon, £80 per annum, two house-physicians, £80 per annum, house-surgeon, £80 per annum, special obstetric physician, £80 per annum, house surgeon to special departments, £80 per annum, dental house-surgeon, £300 per annum. All these appointments are for six months, except that of senior resident medical officer, which is for two years.

Scholarships—The following are among the scholarships and other awards open to students of the school: The Ashworth Hall Scholarship, value £45 open to women only; two Martin Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize value 9 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth year students for general proficiency; the Augustin Prichard Prize value about 6 guineas for proficiency in anatomy; the Henry Clark Prize, value 11 guineas for proficiency in gynaecology; the Crosby Leonard Prize value 7 guineas for proficiency in surgery; the Supple Surgical Prize a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15 for proficiency in surgery; the Sanders Scholarship value £22 10s. for general proficiency; the Barlett Roue Scholarship for proficiency in diseases of the eye, ear, nose and throat, value £14; Lady Habersfield Scholarship value about 25 guineas; Phillips Seppman Prize for proficiency in diseases of children value £50; Bristol City Senior Scholarships and the Senior Scholarships offered by the counties of Gloucestershire, Somerset, Wilts, Devon etc. are tenable in the university.

Some of the Fellowships awarded by the Colston Research Society, for research in the university are allotted to the Faculty of Medicine.

Fees—The fee for all the courses required for the medical curriculum, including hospital practice, is 205 guineas paid by annual instalments.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE

THIS, the Medical School of the Faculty of Medicine of the University of Durham, is in the neighbouring city, Newcastle-upon-Tyne. Its classes and lectures are arranged to meet the requirements of the university in all the degrees which the latter grants, and also those of the other examining bodies. The students do their work in the preliminary sciences at Armstrong College, also part of the university, and their clinical work in the Royal Victoria Infirmary, an institution with about 550 beds and special accommodation for the benefit of students. Students do their practical midwifery at the Princess Mary Maternity Hospital, which contains 80 beds, is thoroughly up to date, and there is an annual indoor and outdoor attendance on 3,000 cases. In a Heath wing of the school itself there is the department of physiology. There are also in this wing a gymnasium and a set of rooms for the use of the Students' Union. A new bacteriological department has recently been erected adjacent to Armstrong College.

Post-Graduate Instruction—A comprehensive series of post-graduate courses has been arranged to enable practitioners to take advantage of the facilities for laboratory work and clinical study which are afforded by the College, the Royal Victoria Infirmary and other associated

hospitals, and in order to meet the varied requirements of practitioners there are general and special courses in the winter and summer session as well as an intensive course in the summer vacation.

Students' Union—Students' Union Buildings have been erected and furnished at a cost of over £40,000, and are now in daily use. Separate accommodation (non-residential) is provided for men and women students.

Appointments—Pathological assistants, and assistants in the eye department, throat and ear department, and department for skin diseases, are elected periodically. Clinical clerks and dressers are appointed every three months.

Scholarships—University of Durham Entrance Scholarship £25 a year for four years, Pears Entrance Scholarship, £40 a year for three years (awarded every third year), Province of Durham Masonic (Entrance) Scholarship £60, Health Scholarship for surgery £200 available every second year.

The following scholarships are tenable for one year—namely, Talloch Scholarship for elementary biology and organic chemistry £20, Dickinson Scholarship for medicine, surgery, midwifery and pathology Gold Medal and £20, Charlton Scholarship for medicine £25, Gibb Scholarship for pathology £28, Jule Armstrong Scholarship for comparative pathology £25, Stephen Scott Scholarship for surgery £40, Philipson Scholarships for highest marks in final M.B. B.S. Examinations two of £48 each, Cowder Memorial Scholarship for clinical medicine and clinical surgery interest on £325, Gibson Prize for midwifery and diseases of women and children £10, Turnbull Prize and Silver Medal for surface anatomy, and Outerson Wood Prize for psychological medicine £10. At the end of each session a prize of books is awarded in each of the regular classes.

Fees—The composition fee for lectures at the college is £122. Composition fee for hospital practice £46 plus £22 a year for three years payable to the Committee of the Royal Victoria Infirmary. Other information should be sought from the Registrar of the College of Medicine at New castle.

LEEDS

The School of Medicine—which is open to both male and female students—in this city forms the teaching centre of the Medical Faculty of the University of Leeds, and is situated in immediate proximity to the General Infirmary, where students sufficiently advanced receive their clinical instruction. The buildings were opened in 1894, and contain excellent dissecting rooms, several well arranged laboratories for physiology, pathology, and bacteriology, three lecture theatres, and several similar classrooms. In addition, there are a library and reading room and two museums, one being devoted to pathology and the other to anatomy. The comfort of the students is secured by common rooms and a refectory in which they can take meals. The General Infirmary has 632 beds, and includes gynaecological and ophthalmic wards, a special children's ward, and a large out-patient department. The Ida and Robert Arthington Semi-convalescent Hospitals, Cookridge, attached to the infirmary have 88 beds. The West Riding Mental Hospital at Wakefield is open for the study of mental diseases. Students can, in addition, attend the practice of the Leeds Public Dispensary, the Hospital for Women and Children, and the Leeds Maternity Hospital, where the obstetric work is done.

Appointments—Surgical dressers are appointed every six months, physicians' clerks, ophthalmic and aural dressers, gynaecological ward clerks, gynaecological out-patient clerks, maternity clerks, assistant physicians' clerk, dermatological clerks and assistant surgeons' dressers. Dressers in the casualty room, post-mortem clerks, and laboratory assistants every three months, and dressers in the venereal clinic every month. After graduation there are a considerable number of residential and other appointments available in the Leeds General Infirmary, Leeds Public Dispensary, Hospital for Women and Children, West Riding Mental Hospital, etc., occupying periods of from six to twelve months at rates varying from £20 to £150 per annum.

Scholarships—The university awards annually a scholarship in the form of a free admission to the lectures and classes given in the university, which are covered by the composition fee. The university also awards a scholarship on the results of the first to the clinical teaching of the infirmary.

Fees—It is estimated by the authorities that the approximate cost of medical education to a student at this university is £360 plus of course the expenses of living during the five years covered

by the curriculum. The fee for a complete course for the first M.B. is £111, the composition fee for the course for the second and third examination, and for the clinical part of the infirmary is £171. The composition and clinical fee for those who have passed the second examination is £138.

Further information can be obtained from the Academic SubDean or Clinical SubDean, School of Medicine, Leeds.

LIVERPOOL

The Medical School of this city is part of the university, and, owing to the enlightened liberality of several men of wealth, is exceptionally well provided with special laboratories, as well as with ordinary spacious and well equipped classrooms and laboratories for the instruction of students proceeding to medical degrees and diplomas in special and ordinary subjects. All the laboratories and other rooms are situated close to one another and interconnected, together forming large blocks of buildings. The work of students throughout all stages of their career is arranged upon very satisfactory lines, and the teaching hospital, of which an account is given below, has amalgamated to form the clinical school of the university.

Appointments—The names of the appointments open to past and other students at this school will be gathered from the account which follows of the hospitals forming the clinical department.

Scholarships—The awards made each year to successful students total over £1500. They include the following: Two Holt Fellowships, one in Pathology, the other in Physiology, a Robert Gee Fellowship in Anatomy, two John Rankin Fellowships in Anatomy, a John A. Garrett International Fellowship in Bacteriology, a Johnston Colonial Fellowship in Biochemistry, an Ethel Lee Fellowship in Gynaecology, and a Thelwell Thomas Fellowship in Surgical Pathology. On Lady Jones Fellowship in Orthopaedic Surgery (value of Fellowships, one at £230, three at £150, one at £120, four at £100), a University Scholarship of £50 awarded on the results of the Second M.B. Examinations, a Scholarship in Mechanical Dentistry of £20, two Lyon Jones Scholarships of the annual value of £21 each for two years, one for the junior and the other for the senior students, the Dealy Exhibition of £15, Chemical School Exhibition of £15, the Owen T. Williams Prize for the Torr Gold Medal in Anatomy, John Rankin Exhibition in Practical Anatomy, £25, the George Holt Medal in Physiology, the Kinethack Medal in Pathology, Mitchell Banks Medal in Anatomy, the Robert Gee Prize of £5 5s. in Children's Diseases, Mary Firth Davies Memorial Scholarship, £60 per annum for four years, Robert Gee Entrance Scholarship, value of £40 per annum for four years, Dental Operating Prizes (four) Orthodontia £15, (two) Samuel Memorial Scholarships three at £20 each, a Thomas H. Boulton Prize in Anatomy, Dr N. I. Robert Prize in Zymotic Diseases, Ash's Prize in Dental Surgery, value £2, Gilmour Medal and other entrance scholarships.

Fees—Information as to the fees for the courses of instruction provided by the schools should be sought from the Dean of the Medical Faculty.

The Clinical School

As many as ten hospitals have combined to form the clinical school of the university, these being: The Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, the Stanley Hospital, the Royal Liverpool Children's Hospital, the Hospital for Women (with the Samaritan Hospital), the Liverpool Maternity Hospital and Ladies' Charity, the Eye and Ear Infirmary, St. Paul's Eye Hospital, and St. George's Hospital for Diseases of the Skin. Between them they provide about 1,445 beds.

MANCHESTER

The staff of the Medical School in this city constitutes the Medical Faculty of the Victoria University, all the arrangements for the instruction of students, both in their earlier and then later studies, being of an elaborate nature. The clinical work of the undergraduates is done chiefly in connexion with the Royal Infirmary, an institution which itself contains about 671 beds, and has associated with it a large convalescent home (136 beds), and the Mental Hospital at Priestwich. Instruction in practical gynaecology and midwifery is given at the Royal Infirmary and the St. Mary's Hospitals.

Appointments—The following are among the appointments open to past and present students of this school in connexion with its arrangements for clinical tuition: Two surgical registrars, at £150 per annum, two pathological registrars, at £100 and £50 per annum, one medical registrar, at £150 per annum, a radiological registrar, at £150 per annum, a surgical tutor, at £30 per annum, a director

for Clinical Work.—The Royal Eye Hospital, the Hospital for Diseases of the Skin, the Manchester Northern Hospital for Women and Children, the well known Hospitals for Children at Pendlebury, and St Mary's Hospital, for Women and Children, all make arrangements for the instruction of students.

University of Wales, and for the degrees and diplomas of other examining bodies. Hospital instruction is given at the Cardiff Royal Infirmary, at the City Lodge Hospital, and at other recognized institutions. The Cardiff Royal Infirmary has 370 beds, and is well equipped in all general and special departments, giving facilities for every branch of study. Medical practitioners wishing to prepare for the Diploma in Public Health or for the Tuberculous Diseases Diploma of the University of Wales can attend complete courses of instruction in the school. Prospectuses can be obtained on application to the Dean of the Faculty of Medicine, or to the Secretary, Welsh National School of Medicine, Newport Road, Cardiff.

SCOTLAND

As will be gathered from the following paragraphs, the facilities for acquiring a medical education in Scotland are very ample, whether the student be proceeding to a university degree or to a diploma. To the descriptions of the different Scottish medical centres in some cases added in account of hospitals which either play an official part in the education given to students as yet unqualified, or offer valuable opportunities for post-graduation work.

ABERDEEN

The school is conducted by the Faculty of Medicine. This comprises twelve chairs, from which instruction is given in all the main branches of medical science—namely, botany, zoology, physics (ordinary and pre-registration), chemistry (ordinary and pre-registration), anatomy, physiology, materia medica, pathology, forensic medicine, surgery, medicine, and midwifery. Courses of instruction in public health and infectious diseases, tropical medicine, medical ethics, and sanatorium treatment of tuberculosis, are conducted by lecturers appointed by the University Court. Special opportunities for practical instruction are afforded in the laboratories and museums attached to the departments.

Clinical instruction is obtained in the Royal Infirmary (accommodating 270 patients), the Royal Mental Hospital (900 patients), the Sick Children's Hospital (85 patients), the City Fever Hospital (250 patients), the General Dispensary, Maternity, and Vaccine Institution (10,000 out-patients annually), and the Ophthalmic Institution (3,000 patients annually). Courses of practical instruction are given in diseases of children at the Sick Children's Hospital, in fevers at the City Fever Hospital, in mental diseases at the Royal Mental Hospital, in diseases of the ear, nose, and throat at the Infirmary and Dispensary, in diseases of the eye at the Infirmary and Eye Institution, in venereal diseases and diseases of the skin at the Royal Infirmary.

The degrees granted in medicine are Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Surgery and Bachelor of Medicine (M.B., Ch.B.). A Diploma in Public Health is conferred after examination on graduates in medicine of any university of the United Kingdom.

The degree of Ph.D. is also granted in this faculty. Bursaries, scholarships, and fellowships, to the number of fifty and of the annual value of £1,180, may be held by students of medicine in this university. They range from £8 to £100 per annum, and are tenable in most cases for two or three years. The winter session begins on November 1, 1925, the summer session on April 20th, 1926.

The fee of 126 guineas is payable for instruction in the university, and the fee for the degrees of M.B., Ch.B. is a considerable sum. The fee for the degrees of M.B., Ch.B. is available in the university, including hospital fees, class and Public Dispensary, Hospital for Women, £236. Riding Mental Hospital, etc., occupy six to twelve months at rates varying per annum.

Scholarships.—The university awards annually of the form of a free admission to the lectures of the Royal the university, which are covered by the common university also awards a scholarship on the examination of the value of £58 in the form of addition to the clinical teaching of the infirmary. **Fees.**—It is estimated by the authorities that the cost of medical education to a student at this university, plus of course the expenses of living during the university year, is about £1,180.

Museum of Science and Art, Physical Laboratory, Chemical Laboratories, Dissecting Room, Bone Room, and Anatomical Museum, Physiological Laboratory, Medical Jurisprudence Laboratories, John Usher Institute of Public Health, Materia Medica Museum and Laboratory, Post-Mortem Department of the Royal Infirmary and University Pathological and Bacteriological Laboratory, Tutorial Classes of Practice of Physics, of Clinical Medicine, and Clinical Surgery, Surgery and Midwifery, and the practice of certain other hospitals.

Fees.—The annual fee for chemistry, anatomy, lectures, physiology, pathology, materia medica, surgery, medicine and midwifery is £6 6 each. Physics, botany, zoology, forensic medicine and public health, £5 5s. Practical zoology, practical anatomy (summer), morbid anatomy, practical materia medica, mental diseases, practical pathology, and medical entomology and parasitology, £4 4s. Experimental physiology, diseases of tropical climates, practical botany, histology, operative surgery, clinical surgery (per term), and experimental pharmacology, £3 3s. Practical anatomy (winter), £6 16 6d. Clinical medicine, £5 15s. 6d. First term subsequent terms, £3 3s. Practical chemistry, £4 11s. 6d. Regional anatomy, chemical physiology, surgical pathology, applied anatomy, and infectious diseases, £1 11s. 6d. Tuberculosis diseases of children, diseases of the eye, diseases of the larynx, ear, and nose, diseases of the skin and venereal diseases, £2 12s. 6d. Advanced bacteriology, £7 17s. 6d. Clinical gynaecology and clinical midwifery, £2 2s.

Scholarships.—There are many funds for the assistance of students by means of bursaries, scholarships, exhibition and money awards from the beginning to the end of their undergraduate career. In addition there are funds which help those who have taken a first degree in medicine and surgery to continue at work as research students. The value of these awards and the conditions attaching to them are so varied that those interested should consult the prospectus of the school itself. No other university is in a better even if as good a position to smooth the financial path of earnest students.

The School of Medicine of the Royal College.—This school is composed of lecturers licensed by the Royal College of Physicians and the Royal College of Surgeons, and also recognized by the university through their *licentia docendi* for the sake of convenience they lecture in separate buildings near to the Royal Infirmary, but form a single corporate body governed by a board consisting of five members elected by the Royal College of Physicians, five members elected by the Royal College of Surgeons, and five members elected by the lecturers in the school. This board, with the assistance of the standing committees of the school, supervises the whole management and especially the maintenance of the efficiency and discipline of the school. The different buildings at present utilized for the purposes of lecturing are the following: (1) Surgeons' Hall, Nicolson Street, (2) New School, Bristo Street, (3) Nicol on Square, (4) Marshall Street and other places. The teaching is similar to that of the Scottish universities, and the students receive similar certificates at the close of each session. The courses on the special subjects not included in the curriculum of the Examining Boards are also conducted by teachers specially qualified in each branch, and have for the last quarter of a century formed a special feature of the school. The fees payable for class and other instruction, and including the sums payable on admission to the examination of the Conjoint Board for the triple qualification, amount to about £180. The Calendar, giving full information regarding classes and fees, can be obtained (price 6d.) on application to the Dean of the School, 11, Bristo Place, Edinburgh.

Women Students in Edinburgh.—Until the close of the summer session of 1916 women students intending to proceed to graduation in the University of Edinburgh, as well as those entering for the triple qualification of the Royal Colleges of Edinburgh and Glasgow, received their training in the Edinburgh School of Medicine for Women. Now women students study under the same conditions as men, and may obtain either the university degree or the diploma of the Royal Colleges. In the university systematic lecture is given to them by the professors in the ordinary classes which are therefore mixed. In Clinical Medicine and Clinical Surgery, however, while the lectures are attended by mixed classes the women students are restricted to the wards of one charge. The particular ward is changed every session, each of the physicians and surgeons to the infirmary taking the women students in rotation. With

few exceptions, prizes, scholarships, bursaries, and similar distinctions are open to women under the same conditions as for men. The women students also have the same privileges as in the past have been given to the men of attending a certain proportion of the extra-mural classes taught by the lecturers of the School of Medicine of the Royal Colleges. Most of the Students' Societies are open to women, with the exception of the University Union and the Royal Medical Society. Their place is taken by the Women Students' Union and the Women's Medical Society. There is also a Women's Athletic Club, with playing fields gifted to it by the university. Information on matters connected with women's studies may be obtained from the Lady Warden, University New Buildings, Edinburgh.

GLASGOW

THE UNIVERSITY SCHOOL FOR MEN—The whole course of study required for graduation (M.B., Ch.B.) at the University of Glasgow can be taken here. Besides ample provision for lectures there is practical and clinical work at the hospitals, and practical courses are conducted in the Pathology, Public Health, Pharmacology, Physiology, laboratories of the following departments: Surgery, Anatomy, Chemistry, Zoology, Physics, and Botany, the Botanic Garden and the Hunterian Museum (Pathology) are also open to students. New buildings and equipments have been provided for botany, zoology, for practical anatomy, for operative surgery, as well as for pathology, the very large additions made a number of years ago to the chemical laboratory rendered it one of the most extensive in Scotland. The classrooms and laboratories for the departments of Physics, Physiology, Pharmacology, Materia Medica, Medical Jurisprudence, and Public Health are also of recent erection, and are elaborately equipped. Four additional chairs of Medicine, Surgery, Obstetrics, and Pathology have been recently established, the professors being specially attached to the Royal Infirmary, and a number of university lectureships in Clinical Medicine, Clinical Surgery, Venereal Diseases, Laryngology, Dermatology, Otolaryngology, Psychological Medicine, Tuberculosis, and Electrical Diagnosis and Treatment have been founded there. Five other chairs have been founded at the university, in Bacteriology, Organic Chemistry, Physiological Chemistry, Applied Physics, Public Health, and another in Pediatrics. There are also lectureships on the Surgical and Medical Diseases of Children and on Electrical Diagnosis and Therapeutics. The university, in short, has made great and successful efforts to extend and improve the accommodation of the medical departments, to strengthen the teaching staff and to encourage post-graduation and research work. A Diploma in Public Health is now also granted. Three very extensive general hospitals in the city afford exceptional opportunities for clinical instruction—namely, the Western Infirmary (600 beds), near the university, to which the Regius Professors are attached, the Royal Infirmary (630 beds), and the Victoria Infirmary (260 beds), while the Royal Mental Hospital, Gartnavel (460 beds), the Royal Hospital for Sick Children (270 beds), the Royal Maternity and Women's Hospital (108 beds), the Glasgow Eye Infirmary (100 beds), the Ophthalmic Institution (35 beds), the fever hospitals at Belvidere (680 beds) and Ruchill (540 beds), and other institutions afford facilities for the practical study of special branches. The large general hospitals of the parish council are now also available for clinical instruction in medicine and surgery. Information regarding post-graduate study will be found at page 441.

Bursaries—Bursaries confined to the Medical Faculty amount in annual value to about £1,000 while bursaries in any faculty amounting to about the same annual sum may be held by students of medicine a number of both sets being open to women. Several valuable scholarships may be held by medical students who have graduated in arts.

The following bursaries are open to undergraduates of both sexes. The Gibb Bursary, annual value £36 tenable for four years. This is open to medical students who are preparing for service as medical missionaries in connexion with the Church of Scotland and will be awarded to the eligible candidate who has gained the highest number of marks in the First Professional Examination. The Arbuthnot Bursary, annual value £30 tenable for three years is awarded by the Senate on the recommendation of the Faculty of Medicine to the student who is of the highest

merit among the candidates as shown by their class records and their performances in the First and Second Professional Examinations. One Logan Bursary, annual value £16 tenable for four years appointment by the Senate. Six Lorimer Bursaries (each £20 and tenable for one year) are awarded to the best students in each of the following classes: botany, zoology, physics, chemistry, anatomy, physiology. The Macintosh Mental Science Bursary, a medicine of the value of £31 is awarded annually to the student (of either sex) attending the class of insanity who ranks first in an examination in that subject the bursar to continue the practical study of the subject to the satisfaction of the Faculty of Medicine. The Gardiner Bursary, annual value £14 tenable for two years will be awarded after the autumn professional examination to the candidate who has passed in physiology at the Second Professional Examination and whose aggregate of marks in that subject and in chemistry and physics of the First Professional Examination is the highest. Of the eight James A. Paterson Bursaries two are awarded each year they are of the value of £30 and £20 respectively and are tenable for four years examination in mathematics and natural philosophy in June for students entering the first and second years of medical study. The following are tenable in any faculty: Four Neilson Bursaries (each £75 and tenable for four years) two Pratt Bursaries (each £20 and tenable for four years) and two Taylor Bursaries (each £10 and tenable for four years). Andrew and Bethune Stewart Bursaries (£50 each tenable for three years) candidates must have taken the M.A. degree of Glasgow. There is a special examination. Nine Glasgow Highland Society Bursaries for students of Highland descent of the annual value of £25 and tenable for five years two vacant each year.

The Carnegie Trust for the Universities of Scotland is empowered to pay the whole or part of the university ordinary class fees of students of Scottish birth or extraction under conditions given in the *University Calendar* and summarized at page 421 of this issue. The Dobbin Smith Gold Medal is awarded for the best essay on a prescribed subject within the science of botany. The Brunton Memorial Prize of £10 is awarded annually to the most distinguished graduate in medicine of the year. The University Commissioners have issued an ordinance to make regulations for the admission of women to certain bursaries, scholarships, and fellowships. Scholarships and fellowships are offered by the Carnegie Trust in science and medicine for post-graduation study. There are also four McCunn Medical Research Scholarships (two of £205 and two of £300) for graduates in medicine of the Scottish universities one Pauls Fellowship for Research in Medical Science of approximately £200 for three years and one Stangor Scholarship value £160 for one year. There is in addition the Caplan H. S. Rankin V.C. Memorial Prize in Pathology.

Fees—The matriculation fee for each year is £2 2s. In no cases the fee for each university class is £6 6s. but in some cases it is £4 4s. For hospital attendance at the Western Infirmary students pay £12 12s for a perpetual ticket or £1 11s 6d for a single term ticket with an additional fee of £5 5s for each winter and £2 12s 6d for each summer clinical course. The fees are the same at the Royal Infirmary. The university fee for the four professional examinations is £34 13s. For the whole curriculum the fees for matriculation class attendance hospital attendance and professional examinations amount to about £250.

For further information apply to the Registrar Glasgow University.

QUEEN MARGARET COLLEGE—In this, the Women's Medical School of the University of Glasgow, the courses of study, degrees, regulations, fees, etc., are the same as for men. Women students have their own buildings, with classrooms, reading rooms, library, etc. They are taught in some classes apart from male students, in others together with them but in either case have all the rights and privileges of university students. Their clinical studies are taken in the Royal Infirmary, where wards containing 520 beds are available for their use, and in its dispensary, and similarly in the Western Infirmary and in the Victoria Infirmary, also in the Royal Hospital for Sick Children, the Glasgow Eye Hospital, the Royal Asylum, Gartnavel, Hawkshead Asylum, the Ophthalmic Institution, the City of Glasgow Fever Hospitals, Belvidere and Ruchill, and the Glasgow Royal Maternity and Women's Hospital.

Scholarship—The Arthur Scholarship, annual value £20 tenable for three years. Open to competition by medical students of first year at the First Professional Examination in October, 1925. This scholarship is restricted to women medical students.

Full information can be obtained from the Mistress, Queen Margaret College Glasgow.

Board for Students—A house of residence for women students, Queen Margaret Hall, is situated near the college, in Bute Gardens. The cost of board and residence is from 32s 6d to 37s 6d a week, according to accommodation. Applications to be made to the Lady Superintendent. Another hostel near the college is South Park House, Ann Street, belonging to the Student Christian Movement, and open to women students of all colleges in Glasgow. Cost of board is from 28s to 30s weekly. Applications to be made to the Warden.

ST MUNGO'S COLLEGE—This is the Medical School of the Royal Infirmary, which is the largest general hospital in Glasgow. The infirmary is situated in Cathedral Square, Castle Street, and has communication with every part of the city. St Mungo's College is in the infirmary grounds, and affords full courses in all the subjects of the medical curriculum, and in all the medical subjects of the dental curriculum.

The infirmary has (including the ophthalmic department) over 700 beds, the average number occupied in 1924 being over 723. There are special beds and wards for diseases of women, of the throat, nose, and ear, venereal diseases, burns, and septic cases. In the out-patient department in 1924 over 44,000 patients were treated. In addition to the large medical and surgical departments, there are departments for special diseases—namely, diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. There is also a fully equipped electrical pavilion, with the latest and most approved apparatus for diagnosis and treatment.

Appointments—Five house physicians and eleven house-surgeons, who must be fully qualified, are appointed every six months, and board in the hospital free of charge. Clerks and dressers are appointed by the physicians and surgeons. As many cases of acute diseases and accidents of a varied character are received, these appointments are very valuable.

Fees—The average class fee is £3 3s for summer classes and £4 4s for winter classes. The fees for all the lectures, practical classes, and hospital attendance necessary for candidates for the diplomas of the English or Scottish Colleges of Physicians and Surgeons amount to about £120. The classes are open to male and female students.

A syllabus of classes can be obtained on application to the Secretary to the Medical Faculty, St Mungo's College, 86, Castle Street.

THE ANDERSON COLLEGE OF MEDICINE—This school provides education in all subjects of the curriculum for both medical and dental students. The school buildings are situated in Dumbarton Road, immediately to the west of the University and Western Infirmary. The hospital practice and clinical lectures are provided in the Western or Royal Infirmary, pathology in the Western or Royal Infirmary, vaccination and dispensary practice in the Western Royal Infirmary Dispensary. These classes are recognized by all the licensing corporations in the United Kingdom, also by the Universities of London, Durham, Glasgow, and Edinburgh (the latter two under certain conditions stated in the school Calendar). The courses (lectures and laboratory) in public health are recognized by the Scottish Licensing Board, the Universities of Oxford, Cambridge, and London, and the London and Irish Colleges.

Fees—The fees for the lectures and practical work required by ordinary students range between 2 and 5 guineas a session. In the Public Health Department the fee for a six months' course is £14 14s. The Carnegie Trust pays the fees of students at Anderson College on conditions regarding which particulars may be obtained from the Secretary, Carnegie Trust Offices, Edinburgh. A Calendar will be sent on receipt of a postcard by the Secretary to the Medical Faculty, the Anderson College of Medicine, Glasgow, who will forward any further information which may be desired.

The Royal Samaritan Hospital for Women, Glasgow, with over 90 beds, offers facilities for clinical instruction in the diseases peculiar to women. Particulars may be obtained from Mr T. Mason Macquharrie, M.A., secretary, 149, St Vincent Street, Glasgow.

ST ANDREWS AND DUNDEE

The medical departments in these two teaching centres enter specially for students proceeding to the degrees of the University of St Andrews, but admit other students as well. In the former city the United College provides education in all subjects for the first two years. In Dundee, University College provides for the needs of students from the beginning to the end of the five years' curriculum. Its buildings are modern, and contain fully equipped laboratories. The clinical work of the school is facilitated by various institutions. The class fees are from £6 6s to £5 12s 6d for systematic classes, and from

£4 14s 6d to £4 4s for practical classes. The hospital ticket is £1 8s for three months, £4 4s a year, or perpetual, £13 6s 8d in one sum. The inclusive or composition fee for the curriculum is £182. In connection with both institutions there are bursaries and scholarships of considerable value, which are awarded after competitive examination. Information as to these can be obtained from the Secretary of the University of St Andrews. Information regarding the clinical facilities may be obtained from the Dean of the Medical Faculty, Medical School, Dundee.

Clinical Work

Good opportunities for clinical work are afforded by the Dundee Royal Infirmary, the instruction given therein being recognized for purposes of graduation by all the Scottish universities, the University of Cambridge, the University of London, the National University of Ireland, and by the Royal Colleges of England and Scotland.

IRELAND

There is a choice of six schools for those pursuing their medical studies in Ireland. For clinical instruction the choice is equally satisfactory and varied, though the hospitals themselves are comparatively small. Some account of the schools follows.

DUBLIN

School of Physics

This school is in Trinity College, Dublin, and is carried on under the joint auspices of the University of Dublin and of the Royal College of Physicians of Ireland. The King's professors of institutes of medicine (physiology), practice of medicine, materia medica, and midwifery being appointed by the latter. Clinical instruction is given at Sir Patrick Dun's Hospital, and some twelve other metropolitan hospitals and asylums are recognized by the Board of Trinity College. The courses of instruction are open to all medical students, whether they belong to the university or not.

The Schools of Surgery

These are carried on in Dublin under the supervision and control of the Council of the Royal College of Surgeons. They are formed of the College's own school combined with two famous old medical schools—Carmichael and Ledwich, they are attached to the College by charter. The buildings contain spacious dissecting rooms, special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories. Advantage can be taken of the lectures and instruction afforded by students otherwise unconnected with the College.

Prizes—Among the prizes annually awarded are The Barker Anatomical Prize (£26 5s), the Carmichael Scholarship (£15), the Mayne Scholarship (£8), the Gold Medal in Surgery, the Stoner Memorial Gold Medal in Anatomy, the H. McNaughton Jones Gold Medal for Midwifery and Gynaecology, class prizes accompanied by silver medals will also be given in each subject. A prospectus can be obtained post free on application to the Registrar, Royal College of Surgeons, Dublin.

University College, Dublin

This is one of the constituent colleges of the National University of Ireland, and at present conducts its work at buildings in Eustace Terrace. It possesses a good library, and the arrangements for the teaching of medical students from beginning to end of the curriculum are adequate. Applications for other information may be addressed to the Secretary and Bursar, University College, Dublin.

Clinical Work

There are numerous well arranged hospitals in and around the city, and almost all of these are recognized for teaching purposes by the Conjoint Board of Ireland, the University of Dublin, the National University of Ireland, and by the bodies elsewhere in the British Isles. Among them are the Mater Misericordiae Hospital, with 345 beds, Dr Stevens's Hospital at Kingsbridge, with 150, Meck's Hospital and County Dublin Infirmary, with 160, Mercer's Hospital, close to Trinity College, with 120, the Royal City of Dublin Hospital, with 124, the Adelaide Hospital, with

140, the Royal Victoria Eye and Ear Hospital, with 100 beds, Sir Patrick Dun's, which has a direct connexion with the School of Physics, and the combined institutions formed by the Hardwicke Fever Hospital, the Rehn and Surgical Hospital, and the Whitworth Medical Hospital, with an aggregate of 230 beds.

As for the famous Dublin medical institution known as the Rotunda Hospital, this practically consists of two distinct hospitals, and is believed to be the largest combined maternity and gynaecological hospital in the British Isles. It receives nearly 3,000 patients every year, and, apart from ordinary out-patient work of a gynaecological order, annually attends some 2,000 women at their own homes during their confinement. It possesses residential quarters for students, and, taken as a whole, offers exceptional opportunities for study both to ordinary students and to medical graduates of any nationality.

BELFAST

THE Medical School is part of the Faculty of Medicine of Queen's University, Belfast, and provides a complete medical curriculum for all purposes. The laboratories in connexion with the departments of biology, chemistry, physiology, pathology, anatomy, physics, and materia medica are all excellent, and there is a Students' Union which gives students the advantages of dining rooms, reading rooms, a library, and various recreation rooms. Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital, which was rebuilt a few years ago and has 300 beds, and the Mater Infirmorum Hospital, which has 150 beds. Other hospitals open to the students of the university are the Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital, the Bessie Ulster Eye, Ear and Throat Hospital, the Union Infirmary and Fever Hospital, the Fever Hospital, Prindysburn, the District Lunatic Asylum, the Samaritan Hospital, Foister Green Hospital for Diseases of the Chest, and the Belfast Hospital for Skin Diseases.

Scholarships—(1) Twelve of the value of £40 each, are assigned as Entrance Scholarships in the Faculties of Arts, Science and Medicine tenable for one year. (2) sixteen Professional Scholarships value from £15 to £10 each. (3) one Hutchinson Stewart Scholarship £12 in mental diseases. (4) one Mackay Wilson Travelling Scholarship £100 awarded triennially. (5) Isabella Tod Memorial Scholarship tenable for three years awarded triennially to a woman student. (6) McGrath Clinical Scholarship awarded annually value about £112. (7) two Musgrave Studentships of £200 in Physiology and Pathology. There is also a post-graduate research fund open to all graduates of not more than three years standing. Gold medals are awarded at the M.D. examination.

Fees—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is approximately £200. This includes examination fees and a perpetual ticket for attendance at the Royal Victoria Hospital or the Mater Infirmorum Hospital and fees for the special hospitals. The course for the Conjoint Board costs about the same amount.

The Regulations of the Medical Faculty containing full information can be obtained on application to the Secretary, Queen's University, Belfast, price 4d.

UNIVERSITY COLLEGE, CORK

THIS institution, formerly known as Queen's College, Cork, is one of the constituent colleges of the National University. It holds examinations for all the faculties of that university, in addition to continuing the work which it has hitherto performed—namely, that of providing education adapted to the needs of medical students at all stages of their career. Its first aim is to fit students for the degrees of the new university, but students proceeding for the examinations of the Conjoint Board of England, Scotland or Ireland, the Society of Apothecaries of London, or the Apothecaries' Hall of Ireland, or London University, can arrange the courses of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance at the college courses are also accepted by the University of Cambridge. Clinical instruction is given at the North and South Infirmarys (each 100 beds) and at the Coll-Union Hospital (1200 beds). Students can also attend the Mercy Hospital (60 beds), the County and City of Cork Lying-in Hospital, the Maternity, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The session extends from October to June.

There is a Dental School in which the degree of Bachelor of Dental Surgery of the National University of Ireland can be obtained. There is a large well equipped dental hospital in connexion with the school.

Scholarships—Over £4,000 is available annually for scholarships in the College. Particulars as to each of them can be obtained on application to the Registrar.

Fees—The fees for the lectures and hospital attendances required by the National University of Ireland course, including examination fees come to about £150.

Further information can be found in the college regulations or obtained on application to the Registrar.

UNIVERSITY COLLEGE, GALWAY

THIS institution is one of the constituent colleges of the National University of Ireland, and includes Faculties of Art, Science, Law, Celtic, Engineering, Commerce, and Medicine. The college buildings are well lighted and well ventilated, and contain dissecting rooms, an anatomical theatre, and laboratories for the study of physiology, chemistry, physics, and other departments of medical science. For pathology and chemistry new laboratories are now provided. It has good grounds surrounding it, and there are many arrangements, such as a library, a college union, and an athletic union, for the benefit of those belonging to the Medical Faculty, as well as for students in other departments of the college. The clinical teaching, which is recognized as qualifying not only for the degrees of the National University, but for those of London University and the diplomas of the various colleges in the three Kingdoms, is carried on at the Galway Central Hospital and the Galway Tuberculosis Hospital. The Galway Central Hospital is a general hospital, and at the two hospitals students have ample opportunities of studying acute and chronic diseases. The Central Hospital has a special ward for diseases of children. Each year the governing body offers about £1,500, and the County Councils of Connaught offer about £3,500, in scholarships. These scholarships are tenable in any faculty. Additional information regarding these scholarships can be obtained on application to the Registrar, and to the Secretaries of the Connaught County Councils.

CLINICAL HOSPITALS IN ENGLAND

MANY hospitals in Great Britain and Ireland, though not connected with any medical school, open their doors either to those who have yet to be qualified, to those who are doing post-graduation work, or to both. The facilities they offer for gaining practical clinical experience are very great, and should not be overlooked. Their honorary staffs commonly make a point of giving such instruction as opportunity offers, and at those situated in the larger towns there are often appointments as clinical assistants to be obtained. In addition, they all have to offer, at shorter or longer intervals, appointments for resident medical officers, house-physicians, and house-surgeons. These are usually paid offices, which may be held for periods varying from six months to a year. Some of those situated in the great medical centres in the provinces, and in Scotland and Ireland, have already been mentioned in speaking of the medical schools in these localities, but it should be added that there are many other provincial hospitals where admirable work is done, and at which much valuable experience can be gained by both senior and junior students, and by those already qualified. Cases in point are the Royal Infirmary, Bradford, the Royal Sussex County Hospital, Brighton, the Royal United Hospital, Bath, the Kent and Canterbury Hospital, the Derbyshire Royal Infirmary, the Royal Albert Hospital and Eye Infirmary, Devonport, the Royal Devon and Exeter Hospital, the West of England Eye Infirmary, Exeter, the Gloucestershire Royal Infirmary and Eye Institution, the Royal Infirmary, Leicester, the County Hospital, Lincoln, the General Hospital, Northampton, the Norfolk and Norwich Hospital, the General Hospital, Nottingham, the Royal Portsmouth Hospital, the Royal Berkshire Hospital, Reading, the Royal South Hants and Southampton Hospital, the Staffordshire General Infirmary, Stafford, the North Staffordshire Infirmary at Hartshill, the Royal Hants County Hospital, Winchester, the Wolverhampton and Staffordshire General Hospital, the County Hospital, York, and the Coventry and Warwickshire Hospital.

London Clinical Hospitals

As for the hospitals in the metropolis, so many of these take a share in the giving of clinical instruction that it is worth while to classify them

General Hospitals—These include the Dreadnought Hospital at Greenwich, and its annex at the Albert Dock, which form the headquarters of the London School of Clinical Medicine, and the London School of Tropical Medicine (now amalgamated with the London School of Hygiene and Tropical Medicine) with its hospital at Endsleigh Gardens, the West London Hospital, Hammersmith, and the Prince of Wales's General Hospital, Tottenham, both of these being described in the article on post graduate work, the Royal Northern Hospital, Holloway Road, an institution containing 135 beds, and the London Temperance Hospital in Hampstead Road.

Children's Hospitals—There are at least seven of these the leader among them being the Hospital for Sick Children, Great Ormond Street, which has 240 beds. There are also the East London Hospital for Children, Shadwell, with 124 beds, the Queen's Hospital for Children Bethnal Green, with 131, the Victoria Hospital for Children, Chelsea with 104, the Belgrave Hospital for Children, which has a considerable out-patient department, but in patient accommodation for only 40 children, the Paddington Green Children's Hospital an institution of about the same size, and the Evelina Hospital for Sick Children, Southwark Bridge Road with 76 beds. The largest and the oldest of the hospitals for both women and children is the Royal Waterloo Hospital for Children and Women Waterloo Road S.E.1.

Hospitals for Women—Queen Charlotte's Maternity Hospital, Marlborough Road, with 70 beds and a residential college for students and practitioners, specializes in the teaching of midwifery. The Samaritan Hospital for Women, Marlborough Road, admits qualified practitioners as clinical assistants to both the in-patient and out-patient departments, demonstrations are given daily in both departments the fees—payable in advance—being £3 3s for three months, full particulars may be obtained from the secretary. In addition may be mentioned the Hospital for Women, Soho Square whose teaching is confined to post graduates in limited numbers, the Chelsea Hospital for Women Athlum Street, Chelsea, and the Elizabeth Garrett Anderson Hospital for Women in Euston Road, the latter being in the nature of a general hospital so far as concerns the class of cases treated.

Eye Hospitals—The largest of these is the Royal London Ophthalmic Hospital. At this hospital two complete courses are given during the year—October to February and the following subjects are taught:—

(1) external diseases, (2) motor anomalies and squint, (3) ophthalmoscopic conditions (weekly classes), (4) pathology practical refraction classes methods of examination (practical), operative surgery, practical pathology practical bacteriology, x-ray and radiotherapy clinical lectures, discussion classes. A fee of 21 guineas entitles the holder to one full five months' course (with the exception of practical pathology and practical bacteriology) together with a permanent ticket for the practice of the hospital. The fee for the practice of the hospital (permanent), £5 5s, for three or six months £3 3s, for two months £2 2s, for one month, £1 1s. Gentlemen are eligible, under certain conditions, for the posts of chief clinical assistant, clinical assistant and junior assistant. Clinical work takes place every morning at 9 o'clock, and operations at 10. An additional special course in the preliminary subjects (namely anatomy physiology and optics) for the D.O.M.S. and other examinations in ophthalmology will be held immediately preceding the date of the examination. The fees for this course will be 12 guineas or £5 5s for any subject separately. Further particulars may be obtained from the Dean of the Medical School. Other eye hospitals are the Royal Westminster Ophthalmic Hospital near Charing Cross, the Royal Eye Hospital, Southwark, and the Central London Ophthalmic Hospital, Judd Street W.C.1, each with about 40 beds.

Fever Hospitals—The Metropolitan Asylums Board has under its control a good many institutions in and around London for the treatment of the more serious zymotic disorders, it makes special arrangements for the instruction of students in this subject, and grants certificates at the end of the courses. Detailed information should be sought from the Clerk to the Board, Victoria Embankment, E.C.4.

Chest Hospitals—The largest of these is the Brompton Hospital for Consumption which has 333 beds and a large sanatorium at Primley with 150 beds. There is also the City of London Hospital for Diseases of the Chest Victoria Park, with 175 beds, and the Royal Hospital for Diseases of the Chest, City Road now amalgamated with the Royal Northern Hospital Holloway Road.

Nose, Throat and Ear Hospitals—The institutions which confine their work to disorders of the throat, nose, and ear all make special arrangements for the benefit of senior and post graduate students. They are the Metropolitan Ear, Nose and Throat Hospital Fitzroy Square, the Royal Ear Hospital, Dean Street, the Central London Throat Nose and Ear Hospital Gray's Inn Road and the Hospital for Diseases of the Throat Golden Square—the last which possesses 75 beds being the largest of the four institutions.

Miscellaneous Special Hospitals—Among these are the Bethlehem Royal Hospital St. Georges Fields S.E.1 which (like the Maudsley Hospital) confines its work to the treatment of mental disorders and includes a department for nervous and early mental disorders. St. Peter's Hospital for Stone and Urinary Diseases which devotes itself to the treatment of diseases of the rectum including cancer and fistula, the National Hospital for Diseases of the Heart in Westminster Street W.C.1, St. John's Hospital for Disease of the Skin in Leicester Square, the Hospital for Diseases

of the Skin Stamford Street Blackfriars, and the National Hospital for the Paralyzed and Epileptic Queen's Square, W.C.1, an institution possessing 200 beds and a world wide reputation.

Detailed information as to the teaching arrangements of all these institutions may be obtained on application to the secretaries.

WOMEN IN MEDICINE

The regulations of the General Medical Council and of the various universities and colleges set out in previous sections apply to women as to men.

Examinations

Women are admitted to all the medical examinations of the following qualifying bodies: the Royal College of Physicians, London, the Royal College of Surgeons of England, the Society of Apothecaries of London, the Conjoint Boards in Scotland and in Ireland, and all the universities of Great Britain and Ireland. The Royal College of Physicians has, during the past year, allowed women to be eligible for election as fellows.

Medical Education

The London (Royal Free Hospital) School of Medicine for Women, which is one of the constituent schools of the Medical Faculty of the University of London, is the sole school for medical education which admits women only. All the resident appointments at the Royal Free Hospital, of which there are nineteen yearly, are held by women. Arrangements are made for students of the School to obtain clinical instruction at the Hospital for Sick Children, Great Ormond Street, the National Hospital for Nervous Diseases, the Royal London Ophthalmic Hospital (Moorgate), the Elizabeth Garrett Anderson Hospital, the South London Hospital for Women, and the Cancer Hospital. Further particulars with regard to the London School of Medicine for Women will be found on page 429.

Women are also admitted to the following men's schools in London: University College Hospital (a limited number only), King's College Hospital, Charing Cross Hospital, and the Westminster Hospital. Further particulars about these schools will be found in the article on London Medical Schools at page 425 et seq. The medical schools of Birmingham, Bristol, Cardiff, Leeds, Liverpool, Manchester, Newcastle, and Sheffield admit women. In Scotland, the medical schools of Aberdeen, St. Andrews, Edinburgh, and Glasgow admit women, although they do not in every case accord them equal facilities with men. The Irish universities and colleges are open to women.

Openings for Medical Women

The London School of Medicine for Women celebrated its jubilee in October, 1924. During the fifty years of its existence over 1,000 women have graduated from this school. At the present time most of them are engaged in active medical work. Unemployment is apparent in all professions, and applies to both sexes, it is asserted that medical women are rather more fortunate in this respect than women in other professions. In private practice they do increasingly well, and are reported to be in great demand as locumtenents for medical men and women.

The Public Health Service, and especially its department of Maternity and Child Welfare, provides openings for women. In addition nearly all the voluntary welfare centres in the country are officered by medical women. The rapid growth in recent years of maternity and child welfare centres has given women, to whom such work is peculiarly suited, an opportunity of participating in this important branch of preventive medicine. Under the Board of Education there are appointments for women as medical advisors and school medical inspectors. The London County Council has medical women as lecturers and examiners on the care of children, home nursing, health, and first aid. Many of the venereal disease clinics have at least one medical woman on the staff. A certain number of appointments as tuberculosis officers are held by women. Appointments are held by women as residents in general hospitals, hospitals for women and children, sanatoriums, infirmaries, fever hospitals, and asylums.

Particulars of the Colonial appointments which may be held by women in British West Africa and the Malay States can be obtained from the Medical Branch of the Colonial Office. Information regarding the women's medical service for India may be obtained from the honorary secretary, United Kingdom Branch of the Countess of Dufferin's Fund, c/o General J B Smith, India Office, Whitehall, S W 1. Missionary societies also offer employment to medical women. Further particulars can, we understand, be obtained from Dr Webb Anderson, Medical Missionary Association, 49, Highbury Park, London, N 5.

Equal Pay for Equal Work

The British Medical Association was the first of all professional organizations to lay down the principle that no distinction should be made on the ground of sex as regards the emoluments to women members of the profession. Attempts are continually being made by public authorities to obtain the services of women doctors at lower salaries than those paid to men, and the Association looks to all medical women to help it in resisting such attacks upon the solidarity of the profession. In its constant efforts to maintain this principle the Association works in close co-operation with the Medical Women's Federation (9, Clifford Street, New Bond Street, W 1). In defence of the principle the British Medical Association has at various times fought—usually with success—Government departments and local authorities of all kinds. Where the authorities concerned have declined to recognize the justice of the claim that equal pay should be given for equal work the machinery, local and central, of the Association has been put into operation, and as a result the authority has generally seen fit to drop the proposed distinction between men and women practitioners or given up the attempt to fill the post. It is hardly necessary to add that the British Medical Association can only be successful in carrying out this policy if it receives the local support of all medical women.

DEGREES FOR PRACTITIONERS

At one time it was almost the universal custom for medical students educated in London and aiming at general practice not to seek a university degree, and as that custom still prevails to a considerable extent a large proportion of medical men in England possess diplomas or licences to practise but not degrees in medicine. This is a fact which they sometimes find reason to regret, and to such practitioners the following paragraphs may be of interest. It should be noted, however, that the M D Bux diploma, if obtained subsequently to June, 1886 is not registrable, and that the University of Brussels no longer holds special examinations for foreign medical practitioners.

UNIVERSITY OF DURHAM

The degree of M D is granted by the University of Durham to registered practitioners of not less than fifteen years' standing, who have been qualified and in practice for that period upon the following conditions without residence. The candidate must be 40 years of age, and must produce a certificate of moral character from three registered medical practitioners. Should he not have passed an examination in arts previous to the professional examination in virtue of which his name was placed on the Register he is examined in classics and mathematics, if otherwise, he is required to translate into English passages from any one of the following Latin authors: Caesar, *De Bello Gallico* (first three books), Virgil, *Æneid* (first three books), or Celsus (first three books). Natives of India or the British Colonies are placed on the same footing as natives of Great Britain. Natives of India must produce evidence from an Indian university that they have passed within one year an examination in Latin.

Professional Examination—The candidate must pass an examination in the following subjects: (i) Principles and practice of medicine including psychological medicine, hygiene, and therapeutics, (ii) principles and practice of surgery, (iii) midwifery and diseases of women and

children, (iv) pathology, medical and surgical, (v) anatomy, medical and surgical, (vi) medical jurisprudence and toxicology. Candidates are examined by means of written papers, clinically, and viva voce, at the College of Medicine, Northumberland Road, Newcastle, and in the Royal Victoria Infirmary. The classical part of the examination may be taken separately from the professional on payment of a portion (£10 10s) of the full fee.

The examinations are held twice a year, towards the end of June and of December. Notice, accompanied by the fee and certificates, must be sent to Professor Howden, Registrar of the University of Durham College of Medicine, Newcastle-upon-Tyne, at least twenty-eight days before the commencement of the examination.

Fees—The fee is 50 guineas, which includes the degree fee. If a candidate fail to pass 20 guineas are retained but if he present himself again 40 guineas only are required.

UNIVERSITY OF BRUSSELS

Dr Jern Willems Secretary of the University of Brussels, informs us that it is possible for a foreigner to obtain in Brussels a diploma of "Docteur en médecine, chirurgie et accouchements" which, though it does not entitle to practise in Belgium, is of the same standard as the Belgian legal diploma.

All candidates are required to submit their degrees or diplomas for consideration to the secretary of the university, and must be prepared to spend a period at the university attending the lectures, clinics, and practical work, before being allowed to enter for the examinations, which are conducted in French, viva voce. The period of residence required will vary according to the standard of the degree or diploma submitted by the candidate for the consideration of the university authorities and may be one, two, or three years. The fees for each year are: Courses, 525 francs; laboratory work, 250 francs; examinations, 110 francs. Dr Arthur Haydon, Honorary Secretary of the Brussels Medical Graduates' Association, 2, Crossfield Road, Eton Avenue, N W 3, will, on application, give further particulars with regard to the preparation for the degree.

POST-GRADUATION STUDY

Those who desire to see established in this country a great organization for post-graduate medical study must have been heartened by the announcement in our issue of August 8th (p. 266) that the Minister of Health had appointed a committee to draw up "a practical scheme of post-graduate medical education centred in London." Something has already been done to crystallize ideas on post-graduate education by the committee appointed by Dr Addison in 1921 with the Earl of Athlone as chairman. Since that committee reported, further experience has been gained by the Fellowship of Medicine and Post-Graduate Association, as well as by the now quite numerous universities, schools, and hospitals in London and the provinces which provide courses for graduates. Moreover, the British Medical Association has appointed a Post-Graduate Committee, which includes amongst its twenty-two members quite a large number of those members of the profession who have been chiefly interested in the question.

The Aim

The aim is to establish in London a real organization capable of affording facilities such as exist even in post-graduate study in Vienna—an organization offering provision for study which will attract men of capacity from the Dominions, America, and foreign countries, offering also courses which will benefit practitioners in this country, whether they wish to perfect themselves in special forms of treatment or to bring up to date their knowledge of general subjects in medicine and surgery. Hitherto progress in the attainment of this aim has been slow. Perhaps there has been a tendency in some of those interested to think in terms of one field of the endeavour rather than of the whole estate in providing for the individual practitioner anxious for a "refresher" course, the imperial idea may have been overlooked. With the evidence that has now been accumulated from all sides

it will be possible for the committee appointed by Mr Neville Chamberlain to take a comprehensive view of the problem. In this country there is no lack of material for post-graduation study, and teachers of outstanding ability are numerous. Moreover, if the ideal of a post-graduate hospital is unrealizable at the moment, for economic or other reasons, there are many institutions available for study, both general and specialized.

The Means

Judging from the discussions which have taken place, organization of post-graduate study would seem to require a central office to which inquiries may be addressed, and from which advice and information may be given, if possible this office should belong to a school with teachers and regular teaching by lectures and clinical work, and with laboratories attached, the school should preferably be attached to a post-graduate hospital for all ordinary clinical and pathological work, arrangements should be made with special institutions for courses in advanced work, there should be a linking up with provincial centres for those who wish to study under a special teacher and for the needs of local practitioners, and a centre for social intercourse, such as a hostel, should be part of the organization.

Many portions of this field have already been cultivated to some extent. Thus the Fellowship of Medicine was established in 1918 for the purpose of drawing together members of all the allied countries for the exchange of medical knowledge and the advancement of medical science. With this body the Post-Graduate Medical Association, founded in May, 1919, was amalgamated in the following October. The Royal Society of Medicine (1, Wimpole Street, W1) generously provided the combined body with an office, from which information regarding post-graduate facilities is given. Moreover, from this office courses of instruction at various hospitals scattered throughout London are organized, and a list of hospitals which welcome the attendance of graduates, with the names of teachers, is published in a *Bulletin*. Permanent schools for those who desire to revise or increase medical knowledge useful in their professional work exist in the West London Post-Graduate College and the North-East London Post-Graduate College. The last named is closely associated with the Fellowship of Medicine. Some of the large undergraduate teaching hospitals in London provide short post-graduate courses. In the provinces the Universities of Oxford, Birmingham, Bristol, Edinburgh, and Manchester, have organized post-graduate courses, general, special, and intensive. Similar courses exist at Glasgow, Newcastle, Leeds, and elsewhere. At Cambridge there is a course at Addenbrooke's Hospital during the Long Vacation. In many places practitioners, during the post-graduate courses, may attend the ordinary medical and surgical practice of the hospital in the locality.

Courses in special diseases can be obtained at a large number of special hospitals. Many of these hospitals are of world-wide renown, and are attended by post-graduate students from all parts of the world. Special note may perhaps be made of the London School of Tropical Medicine, which has now been incorporated in the new London School of Hygiene and Tropical Medicine, of the Liverpool School of Tropical Medicine, and of the Maudsley Hospital, Denmark Hill, S.E.5.

So far, however, there has been no system of linking up these numerous facilities for study, of systematically attracting students from all English-speaking countries to a great school, or of making post-graduate study take a place in civilian practice similar to that which it now takes in the army and navy. Much has been done by voluntary effort, it is to be hoped that the interest now shown by a department of State will succeed in moulding this effort into concrete form.

FELLOWSHIP OF MEDICINE AND POST GRADUATE MEDICAL ASSOCIATION

The Fellowship of Medicine has arranged regular courses in general medicine and surgery, including special departments, each lasting two weeks, they are held once a month, and the fee for each course is 3 guineas (2 guineas for one

week). Courses in diseases of chest, children, heart, nervous system, throat, nose, and ear, dermatology, electrotherapy, gynaecology, proctology, psychological medicine, tropical medicine, ology and venereal diseases, are given from time to time at the special hospitals in association with the Fellowship of Medicine. The Fellowship Programme contains a diary of the arrangements available for post-graduates in various general and special hospitals in London. The programme for the immediate future includes a two weeks' course in general medicine and surgery, from September 21st to October 3rd, at the Westminster Hospital. There will also be special courses in diseases of the chest at the Brompton Hospital from September 21st to October 3rd, in infants' diseases at the Infants Hospital from September 7th to 19th, in dermatology at Blackfriars Skin Hospital from September 7th to 19th, in ophthalmology at the Royal Westminster Ophthalmic Hospital (Charing Cross) from September 7th to 26th, and a course in electrotherapy at the Royal Free Hospital from September 23rd to October 14th. The offices of the Fellowship are, by kind permission of the Royal Society of Medicine, at No. 1, Wimpole Street, W1 (telephone, Mayfair 2263). The secretary is in attendance daily from 10 a.m. to 5 p.m., excepting Saturday. The annual subscription for membership of the Fellowship of Medicine and Post-Graduate Medical Association has been fixed at a minimum of 10s.

WEST LONDON POST-GRADUATE COLLEGE

The work of this institution is carried on at the West London Hospital, the first in London to devote its clinical material solely to the instruction of qualified medical men. The college started in 1895, it is provided with lecture, reading, writing, and class rooms, and accommodation of all sorts for the convenience of post-graduate students. In the five years before the war the work averaged over 220. The work of the college is eminently suitable for men who wish to revise their general clinical knowledge after war work.

As for ward work, the students accompany the senior staff on their visits to the wards at 2.30 p.m. daily, and also go round with the resident medical officers in the morning. Out-patient work begins at 2 p.m. This department is large, and affords ample facilities for post-graduates to see and examine patients. There are the usual special departments. Post-graduates are appointed to act as clinical assistants for three or six months, no charge being made. Special practical classes are held in medicine, general practical surgery, gastro-intestinal surgery, medical and surgical diseases of children, analysis of blood and urine, cystoscopy, venereal disease, tropical diseases, retinoscopy, ophthalmic operative surgery, and, when material is available, in operative surgery. The size of the classes is limited. A special clinic for the treatment of venereal diseases (male and female) is held every evening (Saturdays included) at 5.30. Graduates are admitted to the work of the clinic free, and certificates of satisfactory attendance and work are given.

Operations take place at 2 p.m. daily, the surgeons often availing themselves of the assistance of the graduates, and in any case making arrangements so that they can readily see what is going on. The anaesthetists give instruction in the administration of anaesthetics including spinal anaesthesia, on the operating days, students being allowed to administer them under supervision, while special classes are held in each session. The pathological laboratory is in charge of a pathologist who attends every day. Demonstrations are ordinarily given in the morning by the assistant physicians and surgeons, and by the medical and surgical registrars.

Fees—Hospital practice including all ordinary demonstrations and lectures £1 11s 6d for one week, £4 4s for one month, £7 7s for two months, £9 9s for three months, £15 15s for six months, £23 12s 6d for one year, and £45 for a life ticket. Instruction in the administration of anaesthetics is given at the rate of £3 3s a month.

The certificates of the school are recognized by the Admiralty, the War Office, the Colonial Office, the Indian Office, and the University of London (for higher degrees). A prospectus can be obtained on application to the Dean.

NORTH-EAST LONDON POST GRADUATE COLLEGE

The headquarters of this post-graduate school are situated at the Prince of Wales's General Hospital, in the midst of a densely populated North London district. It contains 200 beds, and is within a few minutes' walk of South Tottenham station, on the London, Midland, and Scottish Railway, and Seven Sisters and Tottenham Hale stations, on the London and North-Eastern Railway. It is readily accessible by electric tram from Finsbury Park and Hackney, and from Dalston, Edmonton, and other parts of North London.

The college is recognized by the Admiralty and the India Office for the purposes of study leave, and by the University of London is a place for advanced study for the M.D. and M.S. degrees, the course of practical teaching of bacteriology is approved by the University of Cambridge for its Diploma in Public Health, and there are ample arrangements for the convenience of men who are thus working, or who, being in active practice, are desirous of getting themselves into touch with modern methods. The hospital as a whole affords excellent facilities for qualified medical practitioners who wish to take part for a time in the work of an active general hospital or to obtain special instruction in the several branches of medicine and surgery, since it is open to them to study diseases of the eye, ear, throat, nose, skin, fevers, children's diseases, psychological medicine, dental surgery, radiography, the application of electricity in disease, and the administration of anaesthetics. Throughout the sessions into which the year's work is divided, clinics, lectures, and demonstrations are given by members of the teaching staff. Operations are performed every afternoon of the week except Saturday. Special vacation or intensive courses are held at intervals throughout the year each lasting two weeks, clinical instruction being arranged for each hour of each day.

Fees—Two guineas for a three months course of study in any one department which may be begun at any time; a fee of 5 guineas admits to the whole practice of the hospital for a similar term (one month 2 guineas and one year 10 guineas) and a perpetual ticket for the practice of the hospital may be obtained for 15 guineas.

The winter session will be opened on October 20th as regards clinical lectures, but the clinical work of the hospital is carried on continuously.

Additional information can be obtained from the Dean of the Post-Graduate College, at the hospital or at 19, Cavendish Square, London, W.1.

NEWCASTLE-UPON-TYNE

For the year 1925-26 the following post-graduate courses have been arranged by the College of Medicine, Newcastle-upon-Tyne (University of Durham):

1 General courses in clinical medicine, surgery and pathology at the Royal Victoria Infirmary meeting once weekly for ten weeks. One course will be held from October to December, and one from April to June.

2 Special courses of clinical instruction meeting once weekly for ten weeks in the following subjects: Gynaecology, diseases of the eye, diseases of the throat, nose and ear, diseases of the skin, venereal diseases, neurology.

Special courses in midwifery will be held at the Princess Mary Maternity Hospital.

3 An intensive course of fourteen days duration in the early part of the Summer Vacation 1926.

4 In addition to the regular post-graduate courses practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary for specified periods.

COURSES FOR MEDICAL GRADUATES AT BRISTOL

The University of Bristol provides courses of post-graduate study for practitioners. Details of set courses at the Royal Infirmary and General Hospital are announced locally. In addition, practitioners may become clinical assistants in medicine, surgery, or special subjects for periods of a month or more.

The university also holds courses of demonstrations in outlying centres in the West of England. Resident practitioners form themselves into a committee and consider the type and extent of demonstrations required. The university furnishes the lecturers and makes all the necessary arrangements. All inquiries should be addressed to the Director of Post-Graduate Studies, Pathological Department, Bristol University.

Daily Post-Graduate Study—For those who are able to devote several hours each day to hospital practice the university offers special facilities for post-graduate work. Qualified medical practitioners may be appointed as clinical assistants for a period of one or more months. They may act as assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, post-graduate and ordinary clinical demonstrations, and post-mortem examinations. Fee £3 3s a month.

Post-Graduate Clinical Work—Demonstration courses with weekly lectures are held during May, June, and July. Fee, £2 2s. All inquiries and applications for admission should be addressed to the Director of Post-Graduate Studies (Clinical Section), Pathological Department, University of Bristol, who can be seen on any day by appointment at the Pathological Department.

Further information as to scholarships, curricula and fees can be obtained from the Dean of the Faculty of Medicine, or the Registrar of the University, Bristol.

EDINBURGH POST-GRADUATE COURSES

In connection with the University and Royal College post-graduate courses are arranged every year, from about the middle of July to about the middle of September, comprising: (a) This year a course in obstetrics and gynaecology was held from July 13th to August 7th, (b) a course on diseases of children from July 13th to 24th, (c) a general medical course, (d) a general surgical course. Courses (c) and (d) extended for four weeks from August 10th to September 5th. Similar courses are held each year.

The course in obstetrics and gynaecology comprises instruction in clinical midwifery and clinical gynaecology, obstetrics and gynaecological pathology, child welfare and ante-natal clinics, etc.

The course on diseases of children includes medical and surgical clinics and special clinics on diseases of the skin, venereal diseases, child welfare, mental defect and throat, dental clinics, and ante-natal clinics. The general medical course includes lecture demonstrations, and, where possible, practical instruction on medical anatomy, medical side-room work, examination of the blood, x-ray and electrical therapy, morbid anatomy, and post-mortem examinations, clinical instruction in medicine, diseases of children, diseases of the skin, and infectious diseases, and special instruction in the diseases and methods of examination of the nervous, circulatory, respiratory, alimentary, and renal systems, and in diseases of the ductless glands. The general surgical course includes lecture demonstrations or surgical anatomy, surgical pathology, and surgical x-ray diagnosis, clinical instruction in surgery at the Royal Infirmary and Royal Hospital for Sick Children, clinical instruction in venereal diseases, surgical out-patients, surgical and gynaecological operations and special instruction in abdominal and genito-urinary and other branches of surgery.

A series of special lectures open to all graduates, is delivered three weeks on subjects of general medical and surgical interest, including recent advances in treatment. Among the special courses also arranged are examination of the blood, vaccine therapy, clinical chemistry, diseases of the ear, nose, and throat and venereal diseases.

Particulars regarding the courses, dates of commencing fees, etc., may be had on application to the Honorary Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

POST-GRADUATE MEDICAL TEACHING IN GLASGOW

Organized post-graduate medical teaching is available in Glasgow under the auspices of the Post-Graduate Medical Association. This association is composed of practically all the teaching institutions in Glasgow and the various teachers giving post-graduate instruction, and its business is managed by a board elected periodically by them. The chairman of the board is Principal Sir Donald MacAlister, Bt., and the vice chairman Sir Hector C. Cameron, D.M.D., the winter months special courses in various subjects are

conducted, and there is a series of weekly demonstrations especially designed for local practitioners. A comprehensive scheme of clinical courses is carried out during the summer months, from May till October, and arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite period throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed.

A general medical and surgical course is now held each year during the last two weeks of August and the first two weeks of September, which is arranged to include most of the subjects of interest to the general practitioner. This year the course is being conducted from August 17th to September 12th. The forenoons are occupied with general medicine and surgical diagnosis and minor surgery, in the Royal Infirmary and in the Victoria Infirmary. In the afternoons special subjects are dealt with in the special hospitals and in the special departments of the general hospitals, two subjects being dealt with each afternoon. On the four Saturday forenoons tuberculosis and infectious fevers are demonstrated at Ruchill Fever Hospital.

Further information may be had on application to Dr James Cusick, Secretary, Post-Graduate Medical Association, 6, Woodside Crescent, Glasgow, C3.

AUSTRALIAN AND NEW ZEALAND MEDICAL ASSOCIATION

The Australian and New Zealand Medical Association gives information and advice to medical visitors from the Commonwealth and Dominions with regard especially to attendance at special clinics, post-graduate work, and facilities for preparing for examinations such as the M.R.C.P., F.R.C.S. (England and Edinburgh), and the D.P.H., and also as to house appointments and clinical assistantships in London and the provinces. Information will also be given as to lodgings, sports, and social opportunities. All medical graduates or undergraduates born in Australia or New Zealand and resident in or visiting England are eligible to become members. The fee is one payment of 5s. Further information can be obtained from the joint honorary secretaries, Mr E. T. C. Miligan, F.R.C.S., and Mr Bedford Russell, F.R.C.S., 86, Huxley Street, London, W 1.

TROPICAL MEDICINE

THERE are large and important schools of Tropical Medicine in London and Liverpool, and several universities and other examining bodies have instituted diplomas or degrees in the subject. The Colonial Office now expects all nominees for the Colonial Medical Service to pass through one or other of the two schools mentioned before their appointments are confirmed, and commercial firms engaged in tropical enterprise commonly demand from medical applicants for employment corresponding evidence of special knowledge. Information with regard to these schools and diplomas and degrees follows.

DIPLOMAS AND DEGREES

LONDON UNIVERSITY—Tropical medicine is one of the six branches in which the M.D. degree may be obtained. The regulations relating to the curriculum and examination correspond to those applying to the other branches.

LONDON JOINT BOARD—This body grants a diploma in tropical medicine to candidates after an examination held in the months of February and July. Candidates must present evidence of having attended, subsequently to obtaining a registrable qualification in medicine, surgery, and midwifery, (1) practical instruction in pathology, protozoology, helminthology, entomology, bacteriology, and hygiene in relation to tropical medicine in an institution recognized for this purpose, during not less than five months; (2) the clinical practice of a hospital recognized for the study of tropical diseases during not less than five months. These conditions may be modified in the case of candidates who have had practical experience in tropical countries. The fee for admission to the examination is £9 9s. The Board also grants diplomas in psychological medicine in ophthalmic medicine and surgery, and in

laryngology and otology. Candidates must hold a medical qualification registrable in the United Kingdom or be graduates in medicine of an Indian, Colonial, or foreign university. Particulars and conditions of admission to these examinations, fees, etc., may be obtained from the Secretary of the Examining Board Examination Hall, Queen Square, Bloomsbury, London, W C 1.

UNIVERSITY OF LIVERPOOL—A diploma in tropical medicine is given by this university to students who have been through the course provided by the Liverpool School of Tropical Medicine and have passed the examination held twice yearly by the university examiners. The subjects of examination are (a) tropical pathology, parasitology, and entomology, (b) tropical and applied bacteriology, (c) tropical hygiene and sanitation, (d) tropical medicine including etiology, symptoms, diagnosis and treatment of tropical diseases. Further information can be obtained from the Dean of the Faculty of Medicine, University of Liverpool. A diploma in tropical hygiene (D.T.H.) has recently been established. The subjects of examination are bacteriology, chemistry (including meteorology and climatology), entomology, protozoology and helminthology, tropical sanitation (including sanitary engineering), practical sanitation. Fee for the course, £15.

UNIVERSITY OF CAMBRIDGE—This university grants a diploma in tropical medicine and hygiene to any person whose name has been on the *Medical Register* for not less than a year provided that he passes the examination of the university in this subject. Previous to admission to the examination he must produce approved evidence that he has studied pathology (including parasitology and bacteriology in relation to tropical diseases), clinical medicine and surgery at a hospital for tropical diseases, and hygiene and methods of sanitation applicable to tropical climates. Examinations are held in January and August each year and last four days. The fee for the examination and diploma is 9 guineas on admission or re-admission. Application for further information should be made to Dr G. S. Graham Smith, Pathological Laboratory, Cambridge.

SCHOOLS

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The London School of Tropical Medicine formerly under the auspices of the Serpentine Hospital Society, was on August 1st, 1924, incorporated by Royal Charter in the London School of Hygiene and Tropical Medicine, and the work of the School continues as the division of Tropical Medicine and Hygiene of the new institution. By the generosity of the Rockefeller Foundation a large sum has been provided for new buildings in Bloomsbury, and for the present the work of the School is carried on in hitherto in the Serpentine Hospital Society's buildings at the Hospital for Tropical Diseases, Lindsley Gardens, N.W. 1, where the specially equipped laboratories, museum library, and clinical facilities afford excellent opportunities to the student and others who may be desirous of studying diseases incidental to tropical climates before entering the service or going abroad. In the wards of the Hospital for Tropical Diseases are to be found cases such as may be met with in actual practice in the tropics. There are two courses in the year, each lasting twenty weeks, beginning October 5th, 1925, and March 15th, 1926, respectively. The course is so arranged as to equip men for the D.T.M. and H. of the Joint Board. There are also advanced courses and a special course in parasitology for D.P.H. students and for the first part of the D.T.M. and H. Camb. Clinical instruction is also provided for the second part of the D.T.M. and H. Camb. Tropical medicine is a sixth alternative subject for the M.D. of the University of London, and the school curriculum is adapted to afford facilities for candidates desirous of taking the M.D. in this subject. Further information may be obtained from the Secretary, London School of Hygiene and Tropical Medicine, 23, Lindsley Gardens, London, N.W. 1.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE

This school is affiliated with the University of Liverpool and with the Royal Infirmary of Liverpool. The university now grants diplomas in tropical medicine (D.T.M.) and in tropical hygiene (D.T.H.).

Two full courses of instruction, each lasting about eleven weeks, are given every year for the D.T.M., commencing respectively October 1st (Autumn term), and January 7th (Lent term), and two courses of the same duration for the D.T.H., beginning on January 7th and April 24th (Summer term). The D.T.H. can only be taken by those who have obtained the D.T.M. Students who do not desire to take the diploma examinations held by the university at the end of each term are given a certificate if attendance has been satisfactory. In addition to these courses, an advanced course of practical instruction in tropical pathology and medical entomology, lasting a month, is given every year in June, it is so devised as to meet the requirements of medical men returning from the tropics on short leave.

Fees—(1) For the D.T.M. or D.T.H. course 15 guineas. (2) For the short advanced course, 6 guineas. (3) For the diploma examinations 5 guineas. An extra charge of one guinea is made for the use of a microscope if required.

The new laboratories of the school adjoin the university and the tropical ward of the Royal Infirmary. The dimensions of the building are 162 feet in maximum length by 84 feet in width. In addition to the basement, in which are accommodated the photographic department and large storage rooms, there are four floors. The ground floor has (1) lecture theatre, with accommodation for about seventy students, (2) library, (3) a spacious museum with preparation room adjoining. The first floor has twelve rooms, in which are housed the Departments of Tropical Medicine and Entomology. The second floor has the main class laboratory, 69 feet by 58 feet, excellently lighted, and three other rooms, devoted to the Department of Parasitology. The third floor has a large research laboratory and two research rooms. On the roof is an insectarium, a mosquito-proof house, and other accommodation.

Since its foundation the school has dispatched to the tropics thirty-two scientific expeditions, many of the workers having been taken from among its students. The work done by the staff has been published in twenty-one special memoirs—in the *Annals of Tropical Medicine and Parasitology*, issued by the school, and in numerous articles in the scientific press.

The school has also two laboratories in the tropics. The Mantos Research Laboratory in Brazil, and the Sir Alfred Lewis Jones Tropical Laboratory in Sierra Leone which was opened on January 10th, 1922, and is staffed by the school. Further information may be obtained from the Honorary Dean, School of Tropical Medicine, Pembroke Place, Liverpool.

PSYCHOLOGICAL MEDICINE

It cannot be impressed too strongly upon the medical student that a knowledge of mental disorder is just as essential as a knowledge of the other forms of disease which he will be called upon to treat in the routine of general practice. It must be understood that by the term "mental disorder" is not only meant those severe forms which are to be found in asylums, but the term also includes mental defectives of all grades, nervous, difficult, and backward children, the mild and often unrecognized psychoses, and also the various types of psychoneurosis. Such disorders provide the general practitioner with a large proportion of his most difficult cases, and he will find a good knowledge of mental disorder invaluable in his work. Apart from general practice, the student who proposes to take up a career in the prison service or, still more importantly, the school medical service, will find a knowledge of psychological medicine an almost essential part of his equipment.

Instruction

Though at the present time the instruction given to the student is far from adequate to supply the knowledge of mental disorder requisite for the needs of the general practitioner, the facilities for the study of psychological medicine in the general hospitals are now much greater than in former years. Thus many of the teaching hospitals have out-patient departments for the treatment of mental cases, and in some of these hospitals special lectures are

given on psychopathology. These facilities need not be utilized by the student, however, and the compulsory part of the curriculum is confined to formal lectures and a few attendances at some mental hospital. Here the student is apt to see mainly the terminal states of mental disease, and he is also apt to gain the impression that mental disorder is necessarily related to segregation and custody. We would therefore impress upon him the importance of attending the out-patient department for mental disorders, where he will be able to observe the mild and early cases such as he will hereafter meet with in general practice.

The Ministry of Health issued in 1923 a memorandum by Sir George Newman on *Recent Advances in Medical Education in England*.¹ The inadequacy of the facilities for the teaching of psychopathology is there commented upon, and it is pointed out that the general practitioner must be competent to diagnose all the chief forms of mental disease and defect (Lunacy Act, 1890, Mental Deficiency Act, 1913, Elementary Education (Defective and Epileptic Children) Acts, 1899 and 1914). The certificates under those Acts are shown to necessitate a diagnosis, a record of the clinical grounds for it, and in some cases the medical reasons for detention or custodial care. It is evident, as Sir George Newman points out, that these requirements are sufficiently exacting to render necessary the proper education in this subject of every medical student, and it should be practical and the subject of examination. The curriculum in mental diseases suggested is as follows:

(i) A short course of lectures in normal psychology, preferably as part of the course in physiology (reflexes, habit, instinct, emotion, intelligence, the conscious and the unconscious mind, Binet tests, investigational methods, etc.).

(ii) Half a dozen explanatory discourses in abnormal psychology, to be taken concurrently with clinical work in mental disease.

(iii) Ten or twelve systematic lectures on mental disease concurrently with clinical work and clinical demonstration at a mental hospital of in-patients pronounced cases (acute or chronic), and the usual types of insanity.

(iv) A series of demonstrations in the out-patient clinic for nervous and mental disorders at the general hospital.

What the student needs is instruction in the etiology, symptoms, diagnosis, treatment and prognosis of the morbid mental states most commonly met in general practice. The student must also be trained in case-taking, the examination of patients dealing with relatives of patients, certification, precautions, etc.

A scheme is now in actual operation at the Middlesex Hospital in which a small number of mental cases are treated in the hospital as in-patients. This is an important move from the teaching point of view, because the student will gain true insight into the relation between mental disorder and medicine as a whole, and he will realize that it is a form of illness to be studied with other diseases and to be treated along similar lines.

In London post-graduate courses of instruction of a comprehensive kind are given at the Maudsley Hospital and at Bethlem Hospital, and at the National Hospital for the Paralyzed and Epileptic, Queen Square, courses are arranged to meet the requirements for the diploma in psychological medicine in regard to nervous diseases. Courses in mental deficiency are arranged by the University of London. There are also post-graduate courses at the Universities of Glasgow, Cambridge, Edinburgh, Birmingham, Leeds, Manchester, Durham, and elsewhere.

Diplomas

Those who are taking up psychiatry as a career will find it desirable to obtain a diploma in psychological medicine. Such a diploma is not at present compulsory for a permanent position on the staff of all mental hospitals, but it will probably become so in course of time, just as it is now essential to obtain the D.P.H. if a career in public health is contemplated. Psychiatry is one of the branches of medicine which candidates for the M.D. degree of the Universities of London and Edinburgh can take up, and, in addition, diplomas in psychological medicine, to which reference has been made, can be obtained from the Universities of Cambridge, London, Edinburgh, Durham, Leeds, Manchester, and the National University of Ireland, and from the Conjoint Board in England. The Medical-Psychological Association of Great Britain and Ireland also

¹ H.M. Stationery Office 1923. To be purchased through any bookseller L. 3d. net.

grants certificates of proficiency after examination, and encourages the study of psychiatry by the offer of prizes for original and research work.

The requirements for a diploma differ to some extent in the various universities and colleges, but the following model scheme suggested by the British Medical Association, and already adopted by the Association of Physicians of Ireland, will give an indication of the scope of the examination for a diploma.

Model Scheme for a Diploma in Psychological Medicine

1 The candidate must be already a registered medical practitioner.

2 The candidate may present himself for examination on the subjects detailed under Part I of the curriculum (see para 4) immediately he has concluded the prescribed courses of instruction, or can produce such other evidence of diligent study of the subjects to be examined upon as may be demanded. Part I must be passed save by special permission at least three months prior to entering for examination on Part II of the curriculum.

3 The candidate may not present himself for examination on the subjects detailed under Part II of the curriculum (see 4) until he has been a registered medical practitioner for not less than two years. He must, subsequently to qualification, have been in the practice of an approved mental hospital for not less than two years or have attended for six months at a hospital, mental or general for clinical instruction in psychological medicine and subsequently held a resident appointment at an approved mental institution or mental wards of a general hospital for not less than six months. In both cases he must produce a certificate from a recognized source that he can apply his theoretical knowledge, and has practical acquaintance with and is well and adequately versed in, the current clinical methods of examination and treatment of nervous and mental disorders. In the case of mental deficiency the certificate should include a practical knowledge of the various intelligence tests and other methods of ascertaining the degree of mental defect. He must also produce evidence of having attended subsequently to qualification courses of lectures demonstrations or other evidence of diligent study of the subjects upon which he presents himself for Part II of the examination as may be demanded.

4 Curriculum. Part I—(a) Anatomy histology and physiology of the nervous system, including the autonomic system anatomy and physiology of the endocrine glands chemistry and cytology of the cerebrospinal fluid. (b) Psychology systematic and experimental. Part II—(a) Verbal anatomy histology and pathology of the systems mentioned under Part I. (a) *post mortem* and laboratory technique. (b) neurology and clinical neurology. (c) psychiatry (including the psychoneuroses) clinical psychiatry and the medico legal relations of mental disorders and mental deficiency. In addition the candidate for Part II will need to show special knowledge of any one subject to be selected by him from the subjects comprising Part I or Part II or may choose to be examined in any one of the following subjects: (d) Mental deficiency and the mental disorders of childhood and adolescence and the duties of school medical officers in relation thereto. (e) Bacteriology as applied to mental and nervous disease. (f) Psycho pathology and psychobiology and their application. (g) The principles of diet vitamins and basal metabolism. (h) Eugenics and vital statistics. (i) Criminology and the jurisprudence of criminal responsibility.

5 The diploma by request may be endorsed that special knowledge has been shown in the subject selected.

6 It is suggested that any compulsory attendance at lectures or demonstrations and clinical courses should be limited to the subjects detailed for Part II and that the course for Part I or Part II should not exceed eight weeks.

Mental Hospital Appointments

Those who take up psychiatry as a career work as medical officers of public or private mental hospitals or similar institutions. Except in the larger institutions, such as those under the control of the London County Council, where a number of the medical officers are allowed to live out if married, the medical staff are resident officers, having board lodging, etc., either in the hospital itself or in residence in the grounds. Junior assistant medical officers receive about £300 to £400 per annum and senior assistant medical officers about £500 to £700, in both cases with board, lodging, laundry, etc., in addition, if married, the board, etc., is commuted for cash. As the mental hospitals are under local control the salaries vary much in different asylums. Medical superintendents, whose pay commonly ranges between £800 and £1500 per annum, are provided with a house in the grounds of the hospital and draw various allowances.

Since the passing of the Asylum Officers' Superannuation Act of 1909 all officers and others of the established staff of a public (county or borough asylum) mental hospital may retire at the age of 55 on a pension varying from one-half to two-thirds of the value of their pay and emoluments, or one-fiftieth for every year served, paying as contribu-

tion 3 per cent of the value of their appointments annually. This very favourable prospect may not appeal to junior practitioners joining the service, but will eventually prove to be a valuable asset.

Prospects in the Public Service

Appointments to the public mental hospitals are made by the visiting committees, and in most cases only the junior posts are open to those who have not had previous experience in psychiatry. Since the public mental hospital service is a local one, except indirectly, not an imperial one, the promotion tends to be slow and uncertain, and the higher positions are not always advertised and thus thrown open to competition. For this and other reasons mental hospital work has undoubtedly not been in favour with newly qualified men in recent years, but the general conditions of service have tended to show a progressive improvement and will in all probability continue to do so in the future.

In March, 1920 the Board of Control did useful service by issuing to visiting committees of asylums a circular upon the three following matters: (a) the dearth of suitable applicants when vacancies occur for the post of assistant medical officer, and the probable causes thereof, (b) the need of provision for the more effective treatment upon modern lines of recoverable cases of mental disorder, (c) the necessity for raising the standard as to the training of existing and future assistant medical officers in asylum practice, and of affording facilities for such training.

Under (a) the Board of Control, after pointing out some of the disadvantages of the present state of affairs, made the following suggestions:

(i) That an improvement be made in the salaries of the assistant medical officers at least to such an extent that in the cases of all those who have been in the service above a certain number of years and are regarded as permanent officials the salary should be reasonably sufficient for a married medical man, and that in the case of the deputy superintendent it should more closely approximate than at present to that of the superintendent.

(ii) That in the case of a permanent official application for permission to marry be not required that according to circumstances proper recommendation for a married man be provided and that subject to rules approved by the Secretary of State for the protection of the patients and with due regard to the proper administration of the institution permission to live out may be granted.

(iii) That to the title of assistant medical officer the words and deputy superintendent should be added to that of the one selected to be in charge during the absence of the medical superintendent.

(iv) That the use of the title "senior assistant medical officer" should not be restricted as at present to the post of first assistant but should be extended and be indicative of a certain standing and expert knowledge. By the adoption of this suggestion there would in many asylums be two senior assistant medical officers and perhaps one or three or four in the largest asylums.

(v) That except where there has been previous asylum experience appointments to posts of assistant medical officers should in the first instance be temporary in character.

Under (b) the Board suggested that the treatment of recent recoverable cases should be carried out by members of the medical staff conversant with modern methods, and that the number of the medical staff should be sufficient to ensure that none of them is required to undertake the treatment of more than fifty recent cases at any one time. Under (c) suggestions were made with a view to encouraging assistant medical officers to obtain a diploma or degree in mental diseases, including provision for study leave on full salary. The attitude of the Board of Control is clearly shown in the following sentence:

If the welfare treatment and recovery of patients is not to be jeopardized and the study of mental diseases is not to lag behind the study of other branches of medicine the Board feel the necessity of initiating measures to maintain progress and to secure the best possible treatment of the patients.

Both the British Medical Association and the Medical Psychological Association are working separately and together to improve present conditions of service, and have, for example, already removed the "celibacy" objection to the service. The salaries have also been considerably increased, especially in the junior ranks, and contrast favourably with those which were paid before the war. During the next few years considerable progress may be anticipated in the conditions under which the insane are treated. The asylums will tend to develop an

atmosphere approximating more closely to that of the general hospitals. If these most desirable changes are brought about, the mental hospital service will become more attractive, and will afford greater opportunities for the medical graduate who proposes to specialize in psychiatry. It may be said that while routine, administrative, and clerical work bulk largely in mental hospital duties, as they do in other public medical services, there is ample material, difficult as the subject may be—in psychiatry as one of the branches of medicine open to young graduates. A change in the law, in which power was given to local authorities to make provision for the treatment of early and acute cases of mental disorder without certification, would do much to make psychiatric work more attractive to medical men. If this alteration in the law were made, hospitals, either in the precincts of the grounds of the county or borough mental hospitals, or in adjacent towns, would be erected in course of time, or winds in general hospitals might be utilized for the same purpose. Such clinics would render appointments in mental hospitals more attractive because the work would be entirely free from the custodial aspects of mental disorder, and attention could be given by the physician to purely medical problems without inhuman legal restrictions.

MAUDSLEY HOSPITAL, DENMARK HILL

A number of courses of instruction for the Diploma in Psychological Medicine have been given at the Maudsley Hospital, the details of the last course being as follows. The course consisted of two parts, Part I being conducted by Sir Frederick Mott, Dr F. Golla, and Dr Henry Deyne. Sir Frederick Mott gave eight lectures on the anatomy of the nervous system, followed by practical distinction and demonstrations on methods of staining nervous tissue and preparing it for microscopical examination. Microscopic sections were distributed, illustrating the principal diseases of the nervous system for mounting as a permanent collection. Dr Golla gave eight lectures on the physiology of the nervous system, followed by practical distinction and demonstrations on physiological chemistry (including the chemistry of the nervous system, physiological contents of reflexes and tremors in man and the action of drugs on the autonomic system). Similarly, Dr Deyne gave eight lectures on psychology, followed by practical instruction and demonstration of psycho-physical methods (including the chemistry of the nervous system, physiological contents of reflexes and tremors in man and the action of drugs on the autonomic system). In Part II of the course Sir Frederick Mott gave six lectures on the pathology of mental diseases, including brain syphilis, its symptomatology and treatment. Dr Bernard Hart gave eight lectures on the psychoneuroses. Sir Frederick Mott and Dr F. Golla gave twelve clinical demonstrations in neurology, the first six demonstrations were given by Dr Golla at the Hospital for Paralysis and Epilepsy, Maudsley, the last six demonstrations were given by Dr Golla at the Hospital for Paralysis and Epilepsy, Maudsley. Dr F. C. Shrubsole gave eight lectures on the practical aspect of mental deficiency. Dr W. C. Sullivan, medical superintendent of Broadmoor Asylum, gave four lectures on crime and insanity. Dr L. Mappothel gave a course of lectures on the differential diagnosis and treatment of mental disorders. The fee for the whole course (Part I and Part II) was 15 guineas, or for either part separately 10 guineas, for one single series of lectures in Part I the fee was 4 guineas and in Part II 2 guineas. Inquiries as to lectures, etc., should be addressed to the director of the pathological laboratory, Maudsley Hospital, Denmark Hill, S E 5.

BETHLEM ROYAL HOSPITAL

A course will be held at Bethlem Royal Hospital, commencing on September 14th of lectures and practical instruction for the Diploma in Psychological Medicine. It is proposed in future to give two courses each year—an autumn session of intensive character commencing in September and completed in early December, and a spring session, commencing in the middle of January and completed in the middle of April. Each course consists of two parts. Part A includes lectures and demonstrations on

the anatomy, histology, and physiology of the nervous system, with lectures on psychology and demonstrations in experimental psychology. Part B comprises lectures and clinical demonstrations in psychology, including lectures and demonstrations in the morbid anatomy of the nervous system, a series of lectures, with clinical demonstrations on different branches of psychological medicine, and lectures, with clinical demonstrations, on mental deficiency. Entrants for the course who pay a composition fee of 15 guineas may, if due notice is given, attend either Part A or Part B of one course and postpone the other part until the next session. An entrant who wishes to attend one part only pays a fee of 10 guineas. An entrant who takes the complete course can attend the general clinical practice of the hospital on payment of 5 guineas for six months, or 10 guineas for one year, but an entrant who does not take either part of the course and desires to attend the clinical practice of the hospital must pay a fee of 5 guineas for each three months of attendance. To enable post-graduates to obtain special experience in this branch of medicine clinical assistants are appointed from time to time. Further particulars may be obtained from the physician superintendent, Bethlem Royal Hospital, S E 1.

NATIONAL HOSPITAL FOR THE PARALYSED AND LEPLECTIC, QUEEN SQUARE

A post-graduate course, which fulfilled the requirements of the regulations for the Diploma in Psychological Medicine in regard to instruction in nervous diseases, was held at the National Hospital for the Paralysed and Epileptic, Queen Square, Bloomsbury, W C 1, in May and June, 1925, and other courses will be duly announced. Lectures on the pathology of the nervous system and various clinical lectures were delivered and demonstrations were given, and out-patient clinics were held at the hospital on the afternoons of Mondays, Tuesdays, Thursdays, and Fridays. An inclusive fee of 9 guineas was charged for the whole course, but any part of the course could be taken separately at a special fee. A special arrangement was made for those unable to attend the whole course, and for details applications should be made to the dean of the medical school. Similar courses are held three times a year—namely, January, May, and October. Special arrangements are made throughout the year for work in the laboratory. Fees are payable to the secretary of the hospital on entering for the course.

THE PUBLIC HEALTH MEDICAL SERVICES

The central authority to secure the preparation, effective carrying out, and co-ordination of measures conducive to the health of the people, and to promote research work and a proper training of persons for health services, is the Ministry of Health.

For the purpose of local public health administration the whole of England and Wales is divided into counties, county boroughs, boroughs, and urban and rural sanitary districts. The administrative County of London, exclusive of the City of London, is divided into twenty-eight metropolitan boroughs.

The public health medical services for Great Britain embrace between three and four thousand medical men and women who give whole-time services, and in addition a large number who give part-time services. The medical officers appointed for these services may be either medical officers of the Ministry of Health for England or of the corresponding Boards of Health for Scotland and Wales, or—and these form the large majority—they may be medical officers appointed by the many local public health authorities. These latter appointments include medical officers of health, tuberculosis medical officers, maternity and child welfare medical officers, venereal diseases medical officers, and school medical officers—for the education authorities must now be regarded as health authorities in respect to the health interests of the school child. By

the larger public health authorities assistant medical officers are also appointed, and these posts often serve as stepping stones to the higher offices as vacancies, which are required to be advertised, occur.

THE MEDICAL SERVICES OF THE CENTRAL AUTHORITY

The Medical Department of the Ministry of Health for England has been organized under the control of a chief medical officer. It contains six sections, with a senior medical officer at the head of each, and altogether fifty medical officers. The sections deal with general health and epidemiology, maternity and child welfare, tuberculosis and venereal diseases, the supervision of food supplies, and sanitary administration in relation to infectious diseases. There is in addition a section concerned with insurance practitioners. Appointments to these posts are not as a rule open to public competition, they are made by the Minister of Health. They are civil service appointments, and come under the civil service superannuation scheme. Medical officers are also employed by the corresponding Boards of Health for Scotland and Wales.

MEDICAL OFFICERS OF HEALTH

The duties of the medical officer of health are to inform himself upon all influences affecting, or threatening to affect, injuriously the public health within his district, to advise his sanitary authority upon all matters relating to health, and to perform all the duties imposed upon him by statutes, by-laws, and regulations. He must prepare and submit to his local authority special and annual reports, give immediate information to the Ministry of Health of any outbreak of dangerous epidemic disease, and, subject to the instruction of his sanitary authority, he shall direct or superintend the work of sanitary inspection.

By the Sanitary Officers Order of 1922 no person is qualified to be hereafter appointed or reappointed as a medical officer of health of any district or combination of districts unless, in addition to the qualifications prescribed by any statute, he is also either registered in the *Medical Register* as the holder of a Diploma in Public Health, Sanitary Science, or State Medicine, or has had not less than three years' previous experience of the duties of a medical officer of health.

The Public Health (Officers) Act, 1921, which was promoted by the British Medical Association, provides that a whole-time medical officer of health of a county borough or urban and rural district in England and Wales, a part of whose salary is contributed by the Exchequer, shall not be appointed for a limited period, and shall not be removed from his office except by or with the consent of the Minister of Health. A similar security of tenure also applies to the medical officers of health of county councils and of London boroughs.

Under the Sanitary Officers Order, 1922, a medical officer of health who does not devote his whole time to the duties of his office, but a portion of whose salary is obtained from Exchequer grant, may be appointed without limit of time, in which case he cannot be removed from office without the consent of the Minister. If he is appointed for a specified term, say one year, he continues to hold office from year to year unless the Minister consents to his removal. Where the electing body pays the whole of the salary of a medical officer of health he may be dismissed from office without reference to the Minister of Health.

A considerable number of authorities have now adopted the Local Government and Other Officers Superannuation Act, 1922. Under this Act if an officer is incapacitated by ill health after ten years of service, or if he has reached 65 years of age, he is entitled to superannuation on the following scale: after ten years' service, 10/60 of the average salary which he received during the last five years of employment, after eleven years, 11/60, and so on up to a maximum of 40/60 after forty years or more of service. The Act, however, remains permissive, and it fails to make due allowance, in computing service for purposes of superannuation, for the more advanced age, as compared with other officers, at which the medical officer of health can enter the public service. In these two respects the position reached falls short of that for which

the British Medical Association has been working for many years.

In Scotland the position is different in some respects. The central authority is the Board of Health, with a staff of medical officers for insurance work. Under the Public Health (Scotland) Act, 1897, no one can be appointed a medical officer of health for any area unless he possesses the Diploma in Public Health. No medical officer can be removed from office except with the sanction of the Board of Health. A "proper" salary must be paid, and the local authority may not bring about the resignation of the officer by indirect means, such as reducing the salary or attaching conditions to the appointment. The Act says nothing about superannuation or the age of retirement.

SCHOOL MEDICAL OFFICERS

School medical officers are appointed by local education authorities. Primarily their duty is to detect among the children attending the public elementary schools any physical or mental defect which may retard education, and to inform their parents of its existence. Most approved schemes of medical inspection include systems of work which facilitate the task of parents in obtaining for their children the necessary treatment, check the results of the treatment, and keep each defective child under skilled observation both at home and at school until it has passed altogether out of the education authorities' hands. Indeed, it is now the practice for the education authorities themselves to provide for certain remedial work, notably the prescription of glasses where necessary, the removal of adenoids and tonsils, and treatment in connexion with certain diseases of the skin. The general object of all schemes alike is to make the inspection imposed by law of benefit, not merely to the individual child, but to the community at large, by preventing conditions which lead to the existence of a large proportion of inefficient citizens among the adult population. The work is so related to that of medical officers of health that, as a rule, the senior school medical officer fills both appointments, his work, when necessary, being supplemented by that of whole- or part-time assistants. A Diploma in Public Health is almost always required of those entering the school medical service.

In Scotland, while the statutory authority for the work of the school medical service is different, the effect is broadly the same.

TUBERCULOSIS MEDICAL OFFICERS

A tuberculosis medical officer is a whole-time officer with special training and experience in tuberculosis work, and of a suitable age and attainments to command general confidence. In England and Wales such officers are appointed by county councils and county borough councils, and their duties are to carry out the work of inspection and diagnosis of tuberculous patients, to advise as to treatment, and to take charge of the work of tuberculosis dispensaries and sanatoriums where these are in operation. The work under tuberculosis schemes is co-ordinated with the general public health work of local authorities, and so the medical officer of health is often appointed as the chief tuberculosis officer when a special tuberculosis officer is on the staff of the local authority. The arrangements in Scotland are very similar.

MATERNITY AND CHILD WELFARE MEDICAL OFFICERS

Any public health local authority, however small, may make arrangements for maternity and child welfare work within its area, although very generally the smaller local authorities are embraced in county council schemes. For the schemes of the smaller local authorities the services of a part-time medical officer are obtained when the medical officer of health does not himself undertake the duties, but for the larger schemes special whole-time appointments are made. The maternity and child welfare medical officer is responsible for the work at the centres provided and for directing the home visitation, and the whole of his work is closely co-ordinated with the other branches of public health work directed by the medical officer of health.

Much of this work was commenced in different parts of the country by voluntary organizations, some of it still

remains in their hands, and is only loosely linked up with the public health local authority, but the tendency is for the whole of it to be undertaken by the local authorities. A large number of women medical officers have been appointed to these posts during recent years.

VENEREAL DISEASES

Schemes for the diagnosis and treatment of venereal diseases are provided and administered by county councils and county borough councils. In some cases the officer is on the staff of the medical officer of health, and in others he is an independent official. Special knowledge and practical experience in the treatment of venereal diseases are essential. The officer appointed for either whole-time or part-time services works at one or more clinics, and also gives instruction and assistance in the treatment of venereal diseases to general practitioners, who are allowed to attend the clinics.

REMUNERATION FOR SERVICES

If we are to have skilled and highly trained medical officials of public authorities it is of course essential that they should receive salaries commensurate with their attainments and bearing a reasonable relation to the amount of time and money that have been expended in fitting them for their important and responsible duties. At present, no standard scale of remuneration for whole-time services has been adopted by public health authorities, although the British Medical Association and the Society of Medical Officers of Health—and more recently the Ministry of Health—have endeavoured to bring this about. The present-day rate of remuneration for the whole-time services of a medical officer of health may be said to vary from £600 to £2,000 per annum, according to the dimensions of the population served and the officer's experience, while the maximum salaries of the principal officers of the medical services are somewhat lower. The whole-time medical officer working under a senior medical officer in most cases receives a commencing salary of £600 per annum, with bonus in some cases. There are good prospects of the adoption in the near future of a recognized scale of remuneration, which will provide a minimum commencing salary of £800 for a chief medical officer of health, of £750 for a chief medical officer of the allied medical services, and of £600 for all medical officers working under senior medical officers—when the officers are not resident in an institution provided by the local public health authority and when they give their whole-time services.

THE REGULATIONS FOR THE DIPLOMA IN PUBLIC HEALTH

By the Regulations or Rules of the General Medical Council, which came into force on January 1st, 1924, the examination for the DPH is divided into two parts, and no candidate is allowed to sit for the final part of the examination until two years have elapsed since a registration qualification was obtained. The object of this two years' interval is "to provide opportunity for candidates for the Diploma or Degree in Sanitary Science, Public Health, or State Medicine, to pass from the state of pupilage to that of responsible practitioners, to give mature consideration to the obligations and duties involved in the work of the Public Health Service, and to require direct experience of medical work in a responsible capacity either in practice or in hospital or laboratory appointments." The examination is both written and oral, and must include practical examination in infectious diseases, food inspection, inspection of premises, dwellings, factories, workshops, schools, etc. Any candidate from the Dominions who possesses qualifications registrable in this country is eligible as a candidate for the examination, given that he has received such a course of training as that defined by the Regulations, at an institution on which is approved by the General Medical Council.

The Curriculum for the Diploma in Public Health. The curriculum must extend over a period of twelve months, and a candidate is admitted to either part of the examination after he has completed the prescribed courses

of instruction in the subjects thereof. At least five months must be given to practical laboratory instruction in an institution approved by the licensing body, in the subjects:—
(1) Bacteriology and parasitology, including entomology, especially in relation to diseases of man and to those diseases transmissible to man from the lower animals (180 hours of such instruction is required).
(2) Chemistry and physics in relation to public health (90 hours of such instruction is required).
(3) Meteorology and climatology (10 hours of such instruction is required).

Therefore at least 280 hours of practical instruction, extending over a period of at least five months, is demanded before a candidate is eligible for Part I of the examination. For a candidate to become eligible for Part II of the examination he must first receive instruction in

- (1) Principles of public health and sanitation (for approximately 30 hours)
- (2) Epidemiology and vital statistics (approximately 20 hours)
- (3) Sanitary law and administration, including public medical services (approximately 20 hours)
- (4) Sanitary construction and planning (approximately 10 hours)
- (5) Every candidate must also have made thirty attendances, of not less than two hours in each week of a three months period at the clinical practice of a recognized hospital for infectious diseases and he must have received instruction in methods of administration
- (6) Every candidate must produce evidence that he has during a period of not less than six months been engaged in acquiring a practical knowledge of the duties routine and special of health administration under the supervision of a medical officer of health who shall certify that the candidate has received from this officer or other competent medical officer during not less than three hours on each of sixty working days during not less than these duties and those relating to:—
(a) Maternity and child welfare service
(b) Health service for children
(c) Venereal diseases service
(d) Tuberculosis service
(e) Industrial hygiene
(f) Inspection and control of food including meat and milk

Certificates of having received the prescribed instruction in public health administration must be given by a medical officer of health who devotes his whole time to public health work, or by the medical officer of health of a sanitary area having a population of not less than 50,000, or in Ireland by the medical superintendent officer of health of a county or county borough having a population of not less than 50,000.

Training Centres for the Diploma in Public Health. Most of the universities of Great Britain and Ireland are training centres for the Diploma in Public Health. The University of London provides an M.D. in State Medicine to its own M.B., B.S. graduates. Candidates who in London at the present time there are few training centres for the DPH than formerly. Candidates who desire to train in London can do so at University College and the Royal Institute of Public Health, and also at the Medical Schools of St. George's and Middlesex Hospitals if a sufficient number of candidates apply for the training.

THE PUBLIC SERVICES. THE NAVY, ARMY, AIR FORCE, AND INDIAN MEDICAL SERVICES

The Medical Departments of the Royal Navy, of the Army, and the Indian Government normally employed between them before the war some 3,000 medical men, and vacancies in the ranks of these services were filled by offering commissions for competition once or more each year. In the abnormal circumstances arising out of the war and the period immediately following it the usual regulations for recruiting the permanent medical staff of these services were, for the most part, in abeyance. The British Medical Association has been for some time, as explained below, in communication with the War Office in regard to several matters in which it considers that medical officers in the Royal Army Medical Corps have been inequitably treated. As no satisfactory reply has been received, young practitioners cannot be advised to join that service. The Association is not satisfied with the conditions offered by the Medical Department of the Royal Navy, but

has agreed for the meantime to waive its objections. The uncertainties of the position with regard to the Indian Medical Service are also explained below. A full statement of the mode of admission and conditions of service in the Royal Air Force Medical Service is given.

ROYAL NAVAL MEDICAL SERVICE

In January, 1920, new regulations for retirement of officers came into force in the Royal Navy, and new rates of pay were laid down. The new regulations inflicted a great injustice upon a considerable number of surgeon commanders who were nearing, or had passed, the new retiring age. The grievances arose under two heads—age of retirement and rate of pension—and frequent remonstrances were addressed to the Admiralty by the British Medical Association.

Very briefly stated, these medical officers, who had entered the service on the understanding that they would be allowed to serve until the age of 55, were compulsorily retired at 50, and their maximum pension was fixed at £600 a year, representing an increase of but 10 per cent on the former retired pay of their rank, it should be particularly observed that officers of other branches got increases of pension varying from 26 to 100 per cent. In reply to representations by the British Medical Association the Admiralty admitted the grievance, and eventually made certain proposals which, after full consideration, the British Medical Association has accepted.

Examinations for direct entry into the Medical Service are at present in abeyance. Letters are made by means of the short-service scheme, and the regulations provide for the transfer to the permanent service of desirable short-service officers. A short-service surgeon lieutenant, after six months' service, may be considered for transfer to the permanent service, and would be permitted to count his seniority from the date of entry for short service for purposes of promotion, increment of full pay, and for retired pay.

General Conditions

A candidate must be registered, must be under 30 years of age, and must be recommended by the dean of his school. Unmarried candidates will be preferred. A candidate will be interviewed by the Medical Director General R.N. and will undergo a physical examination. If considered eligible by the Medical Director General his name will be submitted to the Board of Admiralty, and he may be appointed surgeon lieutenant for short service. A candidate must engage for three years with the option of continuing for a further period of twelve months if his services are still required. The rate of pay is 25s a day or £455 5s a year, with the same allowances as are payable to permanent officers of the same rank. Lodging money at the rate of £80 a year is usually allowed when employed on shore without quarters in the United Kingdom and £56 10s a year in lieu of rations when not victualled in kind. In cases of temporary employment on shore not exceeding thirty days the lodging and provision allowances will be at the rate of 8s and 3s 6d a day respectively. On joining an allowance of £50 for uniform will be made. When the new rates of pay were fixed it was decided that 20 per cent should be considered as due to the then high cost of living. The rates set out above represent a reduction of approximately 54 per cent owing to the decrease in the cost of living. The whole 20 per cent is to be regarded as variable and subject to change on July 1st, 1927, and triennially thereafter either upwards or downwards according as the cost of living rises or falls.

An officer engaged for three years is entitled to receive two months' notice of his services being no longer required. A gratuity of £8 6s 8d will be payable to officers for each completed month of service on completion of their period of service or who are invalided for causes not within their own control before the completion of the prescribed period.

Surgeon lieutenants R.N. for short service intending to apply for transfer to the permanent list must have been under 28 years of age at the time of their entry into the Royal Naval Medical Service.

Full particulars and a form of declaration can be obtained from the Medical Director-General, Admiralty, 68, Victoria Street, London, S.W. 1.

ROYAL ARMY MEDICAL CORPS

The British Medical Association has for some time past been in communication with the War Office with regard to its failure to carry out undertakings it had given as to conditions of service and the amount of pension or gratuity payable on retirement. The Association is anxious that the War Office should be able to recruit suitable medical

men for the Royal Army Medical Corps, and the Naval and Military Committee had an interview with the Secretary of State for War about a couple of months ago. No satisfactory answer has been received, and the matter was discussed at the Annual Representative Meeting on July 21st, when the following resolution was adopted unanimously:

That inasmuch as the provision for a 20 per cent reduction in the retired pay of majors after twenty years' service and the R.A.M.C. Warrant can have the effect of reducing the pension of many of these officers below the sum of £1 a day which was provided by the Warrant under which they joined the Service, the Representative Body is of opinion that a serious breach of faith has been committed by the Government and that therefore the Association is unable to recommend recently qualified doctors to enter the R.A.M.C., and declines to publish the terms and conditions of service in the P.A.M.C. in the Educational Number of the *British Medical Journal*, or in its other publications until the Council is assured that this and other matters under negotiation have been dealt with to its satisfaction.

ROYAL AIR FORCE MEDICAL SERVICE

The Royal Air Force Medical Service offers a career for medical men which should prove both attractive and interesting. The rates of pay and allowances are good, and a new field of scientific interest is opened up by the manifold problems which the circumstances of aviation produce. The physical and mental fitness for, and reaction to, the varied conditions under which the flying personnel perform their functions provide much scope for research.

As promotion to the higher ranks of the service is by selection from officers who are eligible by reason of length of service, and as a certain proportion of the higher ranks will be reserved for purely scientific as opposed to administrative appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in scientific research, as well as for those who develop a talent for administration.

Commission

The establishment will consist partly of permanent and partly of short service officers.

An officer will on first entry be granted a short service commission for a period of three years on the active list (which may be extended to five years at the discretion of the Air Council on the recommendation of the Director of Medical Services) and of four years in the Reserve of Air Force Officers. Selections for permanent commissions will be made from officers holding short service commissions, and those who are not selected will be transferred to the Reserve at the expiration of their period of service on the active list.

Short service officers who are approved for permanent commissions but for whom there are not vacancies in the Royal Air Force Medical Service, may under certain conditions be considered for transfer to the Royal Army Medical Corps. If transferred, their service in the Royal Air Force Medical Service would count towards increments of pay and towards retired pay in the Royal Army Medical Corps.

Officers who have been selected for permanent commissions may be permitted to attend for a period not exceeding nine months a post graduate course in general medicine and surgery, tropical and preventive medicine, and other special subjects. Such permission may be granted during the first six years of permanent service, and when attending these courses officers will receive full pay and allowances.

New entrants into the Royal Air Force Medical Service will be commissioned as Flying Officers (Medical) and will be eligible for promotion to the rank of Flight Lieutenant (Medical) after two years' service. Officers selected for permanent commissions will normally be promoted to the rank of Squadron Leader after ten years' total service. Accelerated promotion may be granted on a limited number of cases, of officers who show exceptional ability after the completion of eight years' service. Promotion within establishment to the rank of Wing Commander will be by selection at any period after sixteen years' total service, and to that of Group Captain by selection at any period after twenty-two years' service.

There will be no competitive examination on entry, and candidates must be under 28 years of age, be British subjects, the sons of British subjects and of pure European descent, be nominated by the dean of a recognized medical school or teaching hospital, and will be interviewed personally by the Director.

TABLE I—Royal Air Force Medical Service Rates of Pay and Allowances

	Pay			Allowances (Daily Rates at Home)						Total Allowances at Home				Total Emoluments at Home

M = Married S = Single

of Medical Services, Royal Air Force, before acceptance. Each candidate must produce

1. Birth certificate
2. Medical registration certificate
3. A declaration containing the following information:
 - (a) Age and place of birth. (1) That he is a British subject, the son of British subjects and of pure European descent. (c) That he is ready to engage for general service at home or abroad as required. (d) The qualifications he is possessed of and what medical or other appointments he has held (if any). (e) That he is willing to fly whenever called upon to do so.

Each candidate will be required, before acceptance, to pass a medical examination to ensure that he labours under no constitutional or mental disease or diseases or weakness, nor any imperfection or disability which may interfere with the efficient discharge of the duties of a medical officer in any climate, in peace or war.

An officer granted a short service commission who, at the time of application for such commission held or was about to hold a resident appointment in a recognized civil hospital, may be seconded for the period not exceeding one year from the date of the commission during which he shall hold such appointment. Whilst seconded he will not receive pay from the Air Ministry funds, but the period of secondment will otherwise count as service in the Royal Air Force, provided that he will be required to serve for a minimum period of three years on the active list from the date on which he ceases to be so seconded.

Uniform and Equipment

Medical officers will be required to provide themselves with the uniform of their rank, and with the distinguishing badges of the Royal Air Force Medical Service. They will be required to provide themselves with service dress and mess dress. The provision of full dress is entirely optional at present. An allowance towards the cost of uniform will be made when the officer has been gazetted, as follows: (a) If he has had no previous service as an officer in H.M. Forces or if any such previous service was terminated more than three years before the date of joining for duty, £50. (b) If he is commissioned within three years of the termination of any previous service as an officer in the Royal Navy, Army, Indian Army, or Royal Marines or any of the auxiliaries of those forces, but not in the Royal Air Force or its auxiliaries, £25. (c) If he is seconded from the Royal Navy, Army, Indian Army, or Royal Marines, £25.

Rates of Pay and Allowances

The rates of pay and allowances at present in force are given in Table I and the standard scale of retired pay for Group Captains and lower ranks in Table II.

TABLE II—The Standard Scale of Retired Pay for Group Captains and Lower Ranks

Age on Retirement	Standard Yearly Rate of Retired Pay	Years of Service	Addition for each Extra Year of Service*	Deduction for each Deficient Year of Service
40	£ 300	17	£ 15	£ 15
41	337	17	15	15
42	375	18	15	15
43	412	18	15	15
44	450	19	15	15
45	487	19	15	15
46	525	20	15	15
47	562	20	15	15
48	600	21	15	15
49	637	21	15	15
50	675	22	15	15
51	697	22	22	15
52	720	23	27	15
53	742	23	22	15
54	765	24	22	15
55	793	24	22	15

* Limited to five years.

The rates of pay (Table I) are liable to revision. The standard rates were drawn up in 1919 in the light of the then high cost of living and 20 per cent of each of the standard rates is regarded as detachable and subject to alteration either upwards or downwards as the cost of living rises or falls. The first revision took effect from July 1st 1924 when a reduction of approximately 5½ per cent was made in the standard rates. Subsequent revisions will be made at intervals of three years.

It must however be clearly understood that while every consideration will be given to the reasonable and legitimate interests of individuals, it will be competent for the Air Council at any time to modify the regulations under which the emoluments of the Royal Air Force are drawn and no officer will be entitled to claim any pay, gratuity or other advantage conferred by a provision being at any time added to, varied, or cancelled.

For the purpose of the issue of allowances a "married officer" is one who is married and has attained the age of 30 or the substantive rank of Squadron Leader or who, irrespective of age and

rank was attained on or before September 15th 1919, and was serving in the Royal Air Force on June 8th, 1922.

As allowances are given for specific purposes the cost of which may vary at comparatively short intervals the rates of allowances are liable to be reviewed as circumstances may require.

A colonial allowance is granted in certain commands abroad in aid of the expenses of living in the countries where the cost is higher than in the United Kingdom.

For periods of service given under Indian administration and payment officers will come under the rates and conditions authorized from time to time by the Indian Government in so far as these rates and conditions may differ from those in this scheme. The Indian rates are at present under review.

Group Captains retire at 55—maximum retired pay £900. Wing Commanders retire at 51—maximum retired pay £600. Squadron Leaders retire at 48—maximum retired pay £500. There will be a minimum qualifying period for retired pay of twenty years.

The rates of retired pay (Table II) (including the maximum rate) are standard rates which will be subject to revision as follows: 20 per cent of each of the standard rates will be regarded as detachable and subject to alteration upwards or downwards as the cost of living rises or falls. The first revision took effect from July 1st 1924 when a reduction of approximately 5½ per cent was made. Subsequent revisions will be made at intervals of three years. The revision will apply to all retired pay which is being drawn at the date of revision as well as to subsequent awards.

Gratuities.—Short service officers will be eligible for gratuities on passing to the reserve on the scale of £100 for each of the first two complete years of service and £150 for each of the third, fourth and fifth complete years. These gratuities will not be payable to officers granted permanent commissions, but the period of service under the short service commission will count for retired pay. Medical officers holding permanent commissions may, at the discretion of the Air Council, be allowed to retire voluntarily from the service after ten years' commissioned service with a gratuity of £1,250 or after sixteen years with a gratuity of £2,000 in lieu of retired pay.

INDIAN MEDICAL SERVICE

As is known from the ordinary sources of information, British rule in India is going through a long period of crisis. The future of all the British services in India is uncertain, and that of the Indian Medical Service not least so. Medical and sanitary subjects were among those specifically mentioned as suitable for transfer to provincial governments in the Montagu Chelmsford report which it may be recalled, was issued over seven years ago. This transfer was effected by the Government of India Act (1919). The Lee Commission, which visited India in the cold weather of 1923-24, to inquire into the prospects and remuneration of the European services, made certain recommendations with regard to the Indian Medical Service in its report issued in May, 1924. They have been considered both by the Government of India and by the Secretary of State for India, but it appears abundantly clear that they will not be accepted by either.

In his speech opening the new session of the Indian Legislature at Simla on August 20th, the Viceroy said that the Government was now taking steps to give effect to the principle laid down by the Joint Select Committee of Parliament that a Minister should have the fullest opportunity of managing that field of government which was entrusted to his care. After stating that recruitment by the Secretary of State for the Indian Educational, Agricultural, and Veterinary services had already ceased, he said: "The problem presented by the Indian Medical Service is more difficult but here, too, the principle of establishing provincial medical services has been accepted, subject to certain conditions, which are still under consideration." This statement leaves many essential points unexplained, and it is to be presumed that publication of the official proposals in their entirety will not be long delayed. When issued they will be examined by the Naval and Military Committee of the British Medical Association, and the decision of the Council of the Association on the advice it gives will be published in due course.

As a matter of fact the India Office is not at present asking for candidates, although it is true that a few commissions have been granted during the last year, one in December, three in January, and nine in March—thirteen in all, a total far from adequate to replace the year's wastage. These commissions have been given on a five years' contract system, which may have a certain attraction for some possible candidates, but is open to many objections, to which due consideration should be given.

Until the facts are fully known and completely discussed it will be inadvisable for a British-born medical man

to become a candidate for the Indian Medical Service offer more than on a short contract, if the objections to that system can prudently be set aside. Remembering what a fine service it has been and what it has done for the people of India, for the profession in India, and for science, it is a sad thing to have to say

PRISON MEDICAL SERVICE

Candidates for the medical staff are approved by the Secretary of State for the Home Office on the recommendation of the Prison Commissioners. The Chairman of the Board is Mr M. L. Waller, C.B. Application for employment may be made to the Board on a special form, which can be obtained from the Secretary, Prison Commission, Home Office London, S.W. 1.

In the smaller prisons the medical officer is usually a local practitioner, but in the larger the members of the medical staff are required to devote their whole time to the service. In the case of those required to give their whole time to the service the appointment in the first instance is to the post of medical officer Class II, and from the seniors of this rank the medical officers Class I are selected as vacancies occur.

In February, 1923, the then Home Secretary appointed a committee to report on what changes, if any, should be made in the remuneration or other conditions of service of officers at the prisons and Borstal institutions in England and Scotland and at Broadmoor Criminal Lunatic Asylum. Evidence was given on behalf of the British Medical Association by the Medical Secretary, who pointed out that the salary offered to Class II medical officers—namely, a basic salary of £300 rising by annual increments—was, even when the allowances and bonus were reckoned in, less than the £500 given the Association looked upon as the minimum commencing salary which should be given to a whole-time medical man holding such a responsible office. The committee issued its report in November 1923. It recommended that officers of both classes should receive an additional £50 a year and from a communication received from the Prison Commission we understand that the pay of the whole-time prison medical staff is: Medical officer Class II, £350 rising by annual increments of £20 to £600; medical officer Class I, £650, rising by annual increments of £25 to £800. Unfurnished quarters are provided or an allowance in lieu is made. The Civil Service bonus is paid on the salary. There are 13 medical officers Class II, 12 medical officers Class I, and 25 part-time medical officers.

The number of vacancies is never large, and promotion is slow.

MEDICAL PRACTICE IN BRITISH DOMINIONS AND FOREIGN COUNTRIES

Medical Acts have now been passed in almost all places forming part of the British Empire beyond the seas and registers of duly qualified practitioners are consequently maintained. To these registers medical men educated in the United Kingdom are always admissible merely on payment of a registration fee, providing they produce evidence that they are of good repute and are either registered or eligible for registration in the United Kingdom, as the local requirement may be. The only exception to this statement that need be made relates to the Dominion of Canada. Each of its provinces acts in medical matters as an independent State. The result has been that reciprocity of practice has been established between this country and all the provinces of Canada except British Columbia, where certain obstacles still remain to be overcome. We would advise any medical man proposing to practise in Canada first to communicate with the Provincial Registrar, stating what degrees or diplomas he holds, and asking for information as to the precise steps he must take in order to obtain admission to the Provincial Register.

Italy and Japan are the only two foreign States with which complete medical reciprocity has been established,

though there are other countries which grant a limited recognition to British qualifications. Generally speaking, in Continental countries (with the exception of the kingdom of Italy) a British medical man desiring to exercise his profession therein must pass practically the same examinations as those imposed on natives of the country. The same observation applies to all foreign States in the South American continent. Each of the United States of North America has its own laws and regulations governing medical practice, some of the States admit any holder of a degree or diploma to their Register, but the majority require a candidate for registration to submit to an examination.

A pamphlet showing the conditions under which medical and dental practitioners legally qualified in their own country may practise abroad can be obtained from the office of the General Medical Council, 44, Hallam Street, Portland Place, London, W.1, price 2s 6d, or 2s 9d post free in the United Kingdom. Practitioners who think of going abroad to practise will find therein much useful information, including the name of the official in each country to whom requests for further particulars should be addressed. The last edition was published in January, 1921.

THE SUDAN MEDICAL SERVICE

THE Sudan, perhaps to a greater extent than any other British possession, is entering on a period of rapid development and expansion, and with this expansion the medical services of the country must necessarily keep pace. The Sudan Medical Service offers many attractions to a young doctor who is interested in his profession and is anxious for professional experience, and to a man fond of an open air life the country offers, in addition, opportunities for every kind of shooting, for fishing, and polo. The staff consists of

- (a) Director Sudan Medical Service Pay £1 500 to £1 600
- (b) Senior Physician Khartoum and Omdurman Civil Hospitals Pay £1 200 to £1 750
- (c) Senior Surgeon Khartoum and Omdurman Civil Hospitals Pay £1 200 to £1 750
- (d) Medical Officer of Health Khartoum Province and Assistant Director Pay £1 200
- (e) A number of senior medical inspectors and medical inspectors who are all British and senior from the outset rises by two yearly increases to £1 080 and thence after three years to £1 200
- (f) A number of Syrian medical officers trained at one of the Syrian medical schools
- (g) A number of assistant medical officers natives of the Sudan

A candidate, on being accepted for the service, becomes a medical inspector. Soon after his arrival in the country he is generally placed in charge of the medical and public health work of a province. His headquarters is the chief town of the province at which there is a general hospital. There are usually smaller hospitals or dispensaries at less important centres in the province, which are under his charge, and which it is his duty to supervise. He will probably have two or three medical officers under his supervision and several assistant medical officers, as well as a sanitary staff.

Besides the ordinary provincial work, there are certain special lines of work. For instance there is a hospital ship working along the various tributaries of the White Nile among the pagan and completely uncivilized natives in those regions, a post which offers great scope for original medical work, and incidentally provides opportunities for big game shooting. There is also the work of organizing campaigns against special diseases endemic in certain parts of the country, such as bilharziasis, anklostomiasis, and yaws.

The country also affords opportunities for research into many interesting problems which urgently need solution in connexion with certain tropical diseases. Kala-azar and the Tropical Research Laboratories afford most ready and cordial co-operation in all such work.

The Sudan comprises an area of over a million square miles, extending from the southern confines of Egypt to the

borders of Uganda and Abyssinia, and from the Red Sea to Vidai and the French and Belgian Congos. In this enormous area are found a variety of different races and a considerable variation of climate. The Sudan may roughly be divided into three zones—a northern, a central, and a southern zone.

1 *The northern desert zone* is hot and dry in the summer, but with cool nights. In the winter the climate is pleasant, and often cold. This region is mainly inhabited by Arab tribes, either sedentary cultivators settled along the river or nomad tribes wandering in the desert with their flocks and herds. There are a few large towns, of which Khartoum, Atbara, and Port Sudan are the most important. Khartoum, with its adjoining towns of Omdurman and Khartoum North, has a population of about 120,000. There are large hospitals at Khartoum and Omdurman. Khartoum has a good electric lighting system and water supply. Many of the gardens have excellent grass tennis courts. Khartoum is connected to Khartoum North by a bridge over the Blue Nile, and a bridge is being constructed over the White Nile, and a bridge Omdurman. An electric tram system is being installed. Port Sudan is a rapidly growing port on the Red Sea. It has a large, well built hospital. Twenty years ago where Port Sudan now is there was only a long creek, with a few nomad Arab tents and some cattle grazing. Now between seven and eight hundred large vessels enter Port Sudan in the course of the year, and this number is steadily increasing. Behind Port Sudan, and parallel with the sea, runs a chain of mountains inhabited by the Hadendaa tribes (the Fuzzy Wuzzies of Kipling's verses), an attractive people, still very independent and shunning contact with civilization. In these mountains, too, the wild sheep can be obtained.

2 *The central zone* for eight months in the year has much the same climate as the northern zone, but has a rainy season of four months (more or less). In this region rain crops are grown over wide areas, and the grazing is excellent. The inhabitants are for the most part Arabs, nomad and sedentary, but with a larger admixture of the black races of the south in their breeding, and in consequence a darker colouring. The area the largest towns are Wad Medani, El Obeid, Kassala, and Gedaref. Wad Medani is the centre of the Gezira irrigated area, an area at present comprising 300,000 acres, but which will eventually extend over an area of three million acres. At Wad Medani there is a newly constructed up to date hospital of two hundred beds, with excellent operating theatres and laboratory. Electric light is being installed. The public health work in the irrigated area is of very great interest. Malaria and dysentery have to be taken against the canals, and precautions have to be taken against the canals becoming infested with bilharziasis. A large sanitary staff is employed for this purpose. Wad Medani is the centre of a considerable English population employed on the irrigated area, and tennis, and, in particular, polo, are played with enthusiasm. About one hundred miles south of Wad Medani at Makwar the Blue Nile dam has been constructed to provide water for the irrigated area to the north. The dam is three kilometres in length. Its construction involved most careful sanitary and anti-malarial precautions, without which the work could not have been carried out. Here, too, is a well built, up to date modern hospital, with accommodation for one hundred and twenty beds.

3 *The southern zone* becomes increasingly tropical in character as the southern boundary of the Sudan is approached. This area is inhabited by negroid peoples, for the most part quite uncivilized, and in many parts difficult to get in touch with, except by means of medical work. Here the sandy soil and the sparse acacias of the northern Sudan are replaced by forest trees and elephant grass. In the place of the gazelle, ibex, and wild sheep of the north are the elephant, the buffalo, and the sitatunga, and the other numerous tropical fauna. There is a large modern hospital at Malakal, a town not far from the old Tashoda, where Marehand and his Cingalese troops fortified themselves after their remarkable journey across Africa, and where they were met by Lord Kitchener after his victory at Omdurman. Excellent medical work, too, is carried out by a hospital ship, which works along the White Nile tributaries. A commencement is being made in the introduction of rain grown cotton cultivation among the more civilized of these tribes, an industry that will in time render this southern area rich and prosperous. In the meanwhile, the region is most interesting, like to the doctor from the point of view of medical work and research, and to the anthropologist, the naturalist, and the hunter.

It will be seen from the above that the Sudan presents a variety of climate, variety of work, and variety of sport, the comforts and opportunities of civilization, often almost side by side with the most primitive conditions, opportunities for medical and surgical work, and for

Inquiries regarding the medical service should be addressed to the Civil Secretary, Sudan Government, Khartoum.

The bulk of the medical appointments made by the Secretary of State in this country are to the Services in the East and West African Colonies and Protectorates, the Straits Settlements and Malay States, the East Indies, and Fiji and the Western Pacific. In general, candidates for such appointments must be between the ages of 23 and 35, and whilst these limits are not for the moment absolute, an officer over 35 years of age on first appointment may be required to serve on a temporary and non-pensionable footing, regular appointments are, subject to a varying period of probation, for the most part, nominally at least, permanent and pensionable. There is no entrance examination, but practitioners selected for appointment must obtain a certificate of physical fitness from one of the Medical Advisers of the Colonial Office. In the case of the West African Medical Staff and the East African Services successful candidates are required to undergo an approved course of instruction in tropical medicine.

While colonial service offers undoubted attractions to some practitioners it also presents very definite disadvantages, and not the least of these is, at the present time, uncertainty as to the future. Before the war, conditions in several of the Services gave rise to considerable anxiety, the greatly enhanced cost of living during the war resulted in a great increase in the cost of living, and the Committee considered the inadequacy of temporary advances in pay. Until the succeeding period of reconstruction, the interdepartmental committee under the leadership of Sir W. Egerton was appointed to consider the means of increasing the remuneration of colonial service generally, and the maintenance of the position of the candidates. The committee recommended that the remuneration of colonial service should be increased by competitive examination, which staff of the Colonial Office by the Director General of the Colonial Service, and more particularly in the East African and Malayan groups.

The condition of the Colonial Medical Services has for some time been a matter of the gravest concern to the British Medical Association, which gave evidence on the subject before the Fegion Committee and has been in constant communication with the Colonial Office on matters touching them well as since August, 1921. During this period the Association has, in effect, been recognized as the mouthpiece of the Services, and has received copies of all official documents primarily affecting medical officers, and also the gazettes of the various local Governments. It has therefore been possible to supplement the activities of the Overseas Branches by the exercise centrally of unceasing vigilance over all tendencies likely to affect the development of the Colonial Services. Present conditions render advisory impracticable in certain branches of the Colonial Service, and especially is this so in the Windward Islands, where three years of unmitting effort on the part of the British Medical Association, both centrally and locally, ended in 1923 in failure. The Representative Body of the Association, after full consideration of the facts of the case, and with a due sense of the responsibility involved in any action tending to hinder the supply of qualified candidates for the Services in the islands, passed at Paris month a resolution regretting that the Colonial Office had

declined to press the claims of the Windward Islands medical officers with regard to their terms and conditions of service, and thoroughly endorsing the action taken by the Council in support of those claims. Such a resolution is the best possible commentary upon the opinion expressed in the *BRITISH MEDICAL JOURNAL* of June 30th, 1923, that no qualified medical practitioner aware of the conditions of service will accept an appointment in these islands. The position in this respect has not been bettered by the modification of the local Medical Ordinance to permit the employment of practitioners not qualified for admission to the *Medical Register* of the United Kingdom.

Our information in respect to the Malayan Medical Service is incomplete, but from that in our possession we are driven to the conclusion that the position is not such as the British Medical Association could approve. The services are under strength, the salaries paid are inadequate, and the administration chaotic. The Colonial Office has had the facts before it for some considerable time, and has in its possession, or ought to have in its possession, reports of commissions of inquiry, but so far has not made public, nor has it communicated to the Association, any decision at which it may have arrived.

East African Medical Service

Beyond the brief reference to this subject on the previous page, attention may be called to the opportunities offered to recently qualified medical men by the East African Medical Service. This service includes Kenya, Uganda, Tanganyika Territory, Nyasaland, Zanzibar, and British Somaliland. In East Africa there is very wide scope for clinical work both medical and surgical, as well as for preventive medicine and sanitation. The field of research is unbounded. The service as a whole is fully alive to its responsibilities and opportunities, individual initiative is encouraged, and the career of a medical officer depends, not on seniority alone, but to a large extent on his own capability. As a rule it is preferable that medical officers on first appointment should not be married, although in all but a few stations conditions allow a medical officer's wife to accompany him. Many posts entail a considerable amount of travelling, which is usually undertaken by motor car. An officer is encouraged to use his own car, and a liberal allowance is granted for running expenses. A large increase in staff of the medical service of Kenya Colony is contemplated for 1926, and there is every likelihood of a number of vacancies for suitable candidates from now onwards. The proposed increase includes both the medical and sanitary divisions of the service, the former is open to those holding ordinary medical and surgical qualifications, post-graduate experience in a hospital appointment being an advantage, posts in the sanitary division will as far as possible be filled by those holding a Diploma in Public Health. Kenya, in the climatic conditions of the greater part of the colony, approximates more to the temperate than the tropical zone. There are many opportunities for all forms of sport and recreation, and life generally is full of interest.

Reference having been made to Kenya Colony in particular, it must be mentioned that a candidate can only apply for appointment to the East African Medical Service in general, he may, however, express his preference for any particular colony, and his wishes will as far as possible be met. It should also be mentioned that the regulations allow for a transfer of a medical officer from one dependency to another, but as a rule such transfer only takes place on promotion or at an officer's own request.

Official Sources of Information

All inquiries in connexion with colonial medical appointments made by the Secretary of State for the Colonies should be addressed to the Assistant Private Secretary (Appointments), Colonial Office, Downing Street, London, S.W.1. Any vacancies occurring in Iraq, Palestine, and Aden are recruited through the Colonial Office, and information can be obtained at the same address. Inquiries about any medical appointments made by the Egyptian Government should be addressed to the Director-General, Public Health Department, Cairo. The Sudan Medical Service is referred to in the article at page 451.

Information as to medical appointments in the self-governing Dominions and their dependencies can be obtained on application to the High Commissioners or Agents General for the Dominions. Intending applicants are also recommended to consult the Colonial Office List and the Professional Handbook (price 6d) issued by the Overseas Settlement Office, 6, St. James's Square, London, S.W.1.

There remain a number of medical appointments made by mining companies and other commercial undertakings in various parts of the tropics. Much caution should be exercised in accepting such posts, and the form of contract should be subjected to very careful scrutiny. Advice in this connexion should always be sought from the Medical Secretary's Department of the British Medical Association, British Medical Association House, Tavistock Square, W.C.1.

MEDICAL RADIOLOGY AND ELECTROLOGY

THE CAMBRIDGE DIPLOMA

A Diploma in Medical Radiology and Electrology is granted by the University of Cambridge. The primary object is to provide adequate training in a branch of medical work which is becoming increasingly important and difficult, and which is outside the ordinary medical curriculum. The diploma is open only to those who hold a medical qualification, and includes a course of lectures and practical work in Physics (Part I) and in Radiology and Electrology (Part II). Attendance at the necessary courses of lectures in both subjects, and in addition six months' clinical experience in an adequately equipped hospital recognized by the Diploma Committee, is essential. The whole course of study takes six months, the lectures, practical work, and hospital attendance running concurrently.

The courses carried out by the University of Cambridge are at present arranged to begin early in January. Three months are spent at Cambridge doing the lectures and practical work in Part I, and attending the systematic lectures in Part II and the practice of Addenbrooke's Hospital, where there is a fully equipped and up-to-date x-ray and electriological department. The remaining three months can be completed at any hospital recognized by the Diploma Committee for this purpose, a list of which can be obtained, but special arrangements are made for students to continue their studies in London, where demonstrations at various hospitals are arranged, in order to give a wide experience.

In addition, an independent course is arranged by the British Institute of Radiology. This course is held entirely in London, but is recognized by the University as qualifying for the examination, it begins early in October.

Further particulars as to the Cambridge courses can be obtained from F. Shillington Seales, M.A., M.D., Medical Schools, Cambridge, and of the London courses from Stanley Melville, M.D., at the Offices of the British Institute of Radiology, 32, Welbeck Street, London, W.1.

MEDICAL MISSIONARIES

Missionary societies are in constant need of qualified men and women to fill vacancies as they occur in their hospitals, and also to enable them to take advantage of fresh openings. To those suitably endowed the mission field offers unique opportunities for interesting work, and the development of native medical schools, as training institutions in connexion with some of the larger mission hospitals, affords excellent scope for valuable work to medical men and women who are qualified to teach. It is not usually expected that medical missionaries should take a position such as would otherwise be occupied by an ordained clergyman or minister, but it is essential that they should be prepared to exert their influence in any hospital to which they may be sent so that a Christian atmosphere may be maintained and the work of evangelization be carried on through the ministry of healing.

As for scientific and other qualifications for the work, medical missionaries, in addition to being physically capable of sustaining a life which makes a great demand upon their strength, should be thoroughly well trained physicians and

surgeons. It is very desirable that they should have held a resident appointment at a general hospital, and have a good knowledge of practical surgery, gynaecology, tropical medicine, and the treatment of eye diseases. Useful information can be obtained from the secretaries of the various Missionary Societies, or from Thomas Cochaine, M.B., C.M., Honorary Secretary British Advisory Board on Medical Missions, 3, India Street, London, E.C.4

Dental Surgery.

UNTIL the passing of the Dentists Act, 1921, the profession of dentistry in this country was regulated by enactments very closely similar to those relating to the practice of medicine—that is to say, there was no direct prohibition of the act of practice, and the Dentists Act of 1878 gave the same degree of protection to legally qualified and registered dentists as was accorded to registered medical practitioners—namely, the reservation of the use of certain titles. This Act also provided (1) that no person should take or use the name or title of "dentist" (either alone or in combination with any other word or words) or of "dental practitioner," or any other name, title, or description expressed in words or by letters implying that he was specially qualified to practise dentistry, unless he was registered, under a penalty of £20, and (2) that an unregistered person could not recover any fee or charge in respect of any dental operation, attendance, or advice. But, in the case of the practice of medicine by unqualified and unregistered persons, certain deterrent factors came into play—such as the inability to give a death certificate—and these did not operate to the same extent in the case of dentistry, hence, unqualified practice has been far more prevalent in dentistry than in medicine, and this increased after a decision of the House of Lords placing a narrow interpretation upon the words "specially qualified to practise dentistry," by defining the word "qualified" as not referring to competence but to the possession of a recognized diploma.

THE DENTISTS ACT, 1921

This unsatisfactory position has now been remedied by the passing into law of the Dentists Act, 1921, its provisions are based largely on the recommendations of a departmental committee appointed in 1917 by the Privy Council "to investigate the extent and gravity of the evils connected with the practice of dentistry and dental surgery by persons not qualified under the Dentists Act." Since November 30th, 1922, no person has been permitted by law to practise or hold himself out, whether directly or by implication, as practising or as being prepared to practise dentistry unless he is on the *Dentists Register* provided for by the Dentists Act 1878. The practice of dentistry is defined as including the performance of any such operation and the giving of any such treatment, advice, or attendance, as is usually performed or given by dentists, and the performing of any operation or the giving of any "treatment, advice, or attendance on or to any person as preparatory to or for the purpose of or in connexion with the fitting, insertion, or fixing of artificial teeth." The maximum penalty incurred by an unregistered dentist is £100 for each offence. There are, however, certain important exceptions to the requirement of registration. A registered medical practitioner may practise dentistry without being on the *Dentists Register*, and a registered pharmaceutical chemist or chemist and druggist may extract a tooth where the case is urgent and where no dentist or dentist is available, but the operation must be performed without any kind of anæsthetic further, any person may carry out minor dental work in a public dental service under the personal supervision of a registered dentist provided it is in accordance with conditions approved by the Minister of Health after consultation with the Dental Board.

Certain persons other than those qualified by examination were entitled to be registered under the new Act. They had to be of good personal character and 25 years of age before July 28th 1921

(the commencement of the Act) and to have been engaged for five of the seven years preceding that date as their principal means of livelihood in the practice of dentistry in the British Isles or have been admitted to membership of the Incorporated Dental Society not less than one year before the commencement of the Act. The passing of the prescribed examination in dentistry within two years of the commencement of the Act is considered as equivalent to practising for five years, and a registered pharmaceutical chemist or a chemist and druggist who immediately before the commencement of the Act had a substantial practice as a dentist including all dental operations, was treated as though he had practised for five years. A dental mechanic who for the five years had been carrying on his work as such and has secured the entry of his name on the list of candidates for examination can be registered provided within ten years of the commencement of the Act he passes the prescribed examination.

Dentistry may be carried on by a corporate body provided the majority of the directors and all the operating staff are registered dentists, and that no business other than dentistry or only as business ancillary to dentistry is carried on by the company. Companies carrying on the business of dentistry at the present time are permitted to continue to do so with certain restrictions provided that the names of the directors have been entered in a list kept by the Registrar for that purpose. Every director or manager of a company convicted of an offence under the Act will be held to be guilty of the offence unless he proves that the offence was committed without his knowledge and the court may in addition to a fine order that the name of any director convicted shall be removed from the list of directors aforesaid.

A subsequent Act passed in 1925 made provision for the registration of persons who were 21 in November 1921 who had served during the late war in His Majesty's Forces and were on that date engaged as their principal means of livelihood in the practice of dentistry in the British Isles. The Board however has now power to consider any further applications under this Act.

THE DENTAL BOARD

The Dental Board of the United Kingdom was established for the purpose of administering the new Act. The first members of the Board, who held office for three years, were all appointed, but their term has now come to an end. The Board consists of the chairman, appointed by the Privy Council, three members appointed by the General Medical Council, who must be members of the Branch Councils for England, Scotland, and Ireland, respectively, three persons who are neither medical practitioners nor dentists, appointed to represent England, Scotland, and Ireland, and six elected members, one of whom represents the qualified dentists in England and Wales, one those in Scotland, and one those in Northern Ireland, and two all the dentists registered under the Acts of 1921 and 1923.

On the establishment of the Dental Board in 1921 certain powers and duties of the General Medical Council were transferred to it, including the duty of erasing from the *Dentists Register* any entry which has been incorrectly or fraudulently made. An inquiry into the case of a person alleged to be liable to have his name erased from the *Register* will be made by the Board, which will report its findings to the General Medical Council, the order directing the erasure being made, as at present, by the Council. A name erased from the *Register* can only be restored by the Council upon a report made by the Board. An appeal to the High Court may be made by any person aggrieved either by refusal of the Board to register his name or by the removal of his name from the *Register*. The administrative expenses of the Board are defrayed from the registration fees and annual retention fees, but any surplus may be allocated to purposes connected with dental education and research or to any public purpose connected with dentistry. The office of the Dental Board is at 44, Hallam Street, London W.1.

The *Dentists Register* for 1925 contains the names of 13,818 persons, of whom less than a half are registered with qualifications, 7,296 names having been registered under the Dentists Acts, 1921 and 1923.

DENTAL EDUCATION AND EXAMINATION

The preliminary examination in arts is the same for medical and dental students, and the early stages of their education embrace much the same subjects, and, as the dental student is required to obtain a knowledge of the broad principles of medicine and surgery, it is necessary for him to pursue some portion of his studies at a medical school as well as at a special dental school, the latter not

¹ See the Registrar's Memorandum printed in the article on the General Medical Council at page 411.

undertaking the teaching of these subjects. Registration of a dental student is not in all cases compulsory, though it is to be advised as convenient as affording proof of the commencement of professional education, and it is required by most of the licensing bodies, all of whom insist upon a curriculum covering four academic years.

Qualifying licences are granted by the Royal Colleges of Surgeons of England and of Edinburgh and of Ireland, by the Royal Faculty of Physicians and Surgeons, Glasgow, and by certain of the universities in Great Britain and Ireland.

Recognized dental schools are numerous. In London there are those connected with the Royal Dental Hospital, Leicester Square, the National Dental Hospital (now the University College Hospital Dental School), Great Portland Street, Guy's Hospital and the London Hospital. In the provinces there are the Birmingham Dental Hospital, the Royal Infirmary and the General Hospital, Bristol, the Dental Hospital and the Public Dispensary, Leeds, the Dental Hospital, Liverpool, the Dental Hospital, Manchester, the Dental Hospital and School, Newcastle upon Tyne, the Royal Hospital, Sheffield. In Scotland there are the Dental Hospital, Dundee, the Incorporated Dental Hospital and School, Edinburgh, and the Incorporated Dental Hospital, Glasgow, and in Ireland the Incorporated Dental Hospital of Ireland and the Royal College of Surgeons in Ireland.

Study may also be commenced in the dental department of any university of the United Kingdom. The universities mentioned in the *Medical Directory* as possessing dental schools or departments are Birmingham, Leeds, Liverpool, Manchester, and Sheffield.

There are considerable variations in the order in which the different licensing bodies require the various subjects of the curriculum to be taken up, and every prospective dental student should study, not only the regulations of the General Medical Council, but also those of the body whose licence he hopes to obtain. Thus, as the more important as in the case of some licensing bodies changes in the curriculum have been made or are contemplated.

Recommendations of the General Medical Council

The Dentists Act still leaves to the General Medical Council the duty of controlling the course of study and examinations required for dental qualifications.

The following recommendations as to the course of study and examinations to be required of candidates for degrees or licences in dentistry or dental surgery were adopted by the Council on May 27th, 1922.

Preliminary Examination and Registration

1. That every dental student shall at the commencement of his studentship be registered in the manner and under the conditions prescribed for medical students.

2. That before registration in the *Dental Students Register* every applicant shall be required to have passed in addition to the examination in general education which shall be the same as that required for medical students an examination in Elementary Physics and Elementary Chemistry conducted or recognized by one of the licensing bodies which shall also be the same as that required for medical students.

3. That before registration as a dental student every applicant shall produce evidence that he has attained the age of 17 years.

Professional Study

4. That every candidate for a degree or licence in dentistry or dental surgery shall be required before admission to the final or qualifying examination to produce certificates showing

- (i) That he is at least 21 years of age.
- (ii) That he has been registered as a dental student.
- (iii) That he has subsequently to the date of registration as a dental student been engaged in professional study for at least four years of which three years at least shall be spent at a school or schools recognized for professional study by one of the licensing bodies.
- (iv) That subsequently to the date of registration as a dental student he has attended at a recognized medical school courses of instruction which shall be the same as those required for medical students in the following subjects: (a) Chemistry, and (b) Physics in their application to Medicine, (c) Elementary Biology. That he has attended at a recognized medical school courses of instruction in the following subjects: (d) Human Anatomy (with dissections and demonstrations) for three academic terms, (e) Physiology (with laboratory instruction including Practical Histology) for two academic terms, (f) General Pathology (including Bacteriology) for two academic terms, (g) Medicine for two academic terms, (h) Surgery for two academic terms, (i) the practice of a recognized general hospital or hospitals of not less than eighty beds with certified instruction in Clinical Medicine and Clinical Surgery for four academic terms.
- (v) That he has attended at a recognized dental school courses of instruction in the following special subjects: (a) Dental Anatomy and Physiology, human and comparative. The course should comprise a minimum of twenty meetings of the class. (b) Practical Dental Histology and Micro-bid Histology. The course should comprise a minimum of sixteen meetings of the class. (c) Dental Pathology and Surgery. The course should comprise a minimum of twenty meetings of the class. (d) Dental Materia

Medica and Therapeutics. The course should comprise a minimum of sixteen meetings of the class. (e) Dental Metallurgy (with practical work and demonstrations). The course should comprise a minimum of twenty meetings of the class. (f) Dental Mechanics (with practical work and demonstrations). The course should comprise a minimum of twenty meetings and twenty demonstrations. (g) A course of instruction in the use of anaesthetic general and local, employed in dental practice. (h) A course of instruction in Radiology as applied to dentistry.

(vi) That he has for at least twenty-four calendar months attended, during the ordinary academic terms, the practice of a recognized dental hospital or of the recognized dental department of a general hospital.

(vii) That he has received for not less than twenty-four calendar months, or for 2,000 hours, practical instruction in dental mechanics.

Professional Examinations

5. That the examination for a degree or licence in dentistry or dental surgery shall be partly written, partly oral, and partly practical, and shall include the following subjects: (a) Chemistry, Physics and Biology, in their bearing on Medicine and Dentistry, (b) Human Anatomy and Physiology, (c) General Pathology, including Bacteriology, (d) Medicine and Surgery, (e) Dental Anatomy, (f) Dental Pathology, Dental Surgery (including Dental Medicine and Therapeutics), (g) Dental Metallurgy, (h) Practical Examination in Dental Mechanics and Metallurgy, (i) Anaesthetics general and local employed in dental practice.

6. That the prescribed subjects of examination may be combined or distributed at the discretion of the licensing bodies and may be taken at two or more successive stages during the course of professional study provided that no candidate shall be admitted to any final examination in dental surgery and dental mechanics until he shall have completed the required four years' course of study.

MEDICAL REGISTRATION IN THE IRISH FREE STATE

DECISION TO SET UP A SEPARATE REGISTER

An announcement was made on August 15th on behalf of the Free State Government to the effect that it had decided to set up a separate *Medical Register* for the Irish Free State. The matter had been under discussion for about two years, and last year a bill was introduced into the Dáil sanctioning the continuance of the powers of the General Medical Council in respect of the Irish Free State for a period of twelve months. On February 23rd last this measure, continuing the pre-existing arrangements as to medical registration for a year from that date, was enacted by the Free State Legislature. The effect of the Act (to quote the words of Sir Donald MacAlister in the course of his Presidential Address to the General Medical Council last May) was to provide that in Southern Ireland the Council's constitution and powers, and the powers and responsibilities of its universities and corporations, should, so long as the Act was operative, continue to be regulated by the Medical Acts, as they were regulated before the Irish Free State was established. "It is, of course" (Sir Donald MacAlister continued), "open to the Free State, if it thinks fit, to renew the Act for a further period before its expiry in February, 1926. No similar Act has been passed relating to the dental profession, and accordingly the jurisdiction of the Council and of the Dental Board over dentists in the Free State has come to an end."

The unexpected decision of the Executive Council of the Free State Government to establish a separate *Medical Register* for the Irish Free State has aroused the very strong opposition of an almost united medical profession. Medical protests have been supported by the daily press in Dublin and elsewhere, and the general opinion is that a serious error of policy has been committed by the Executive Council. The situation has been described and discussed in recent issues of the *BRITISH MEDICAL JOURNAL*—August 22nd (p. 353) and August 29th (p. 356). As the matter is one which concerns very closely the future of medical education in Ireland, it seems appropriate to include in this Educational Number further expressions of opinion of which reports have come to hand this week from responsible medical quarters in the Irish Free State.

PROTEST BY THE PROFESSION IN IRELAND

Members of the medical profession in Cork, including professors of University College, Cork, have addressed the following circular to candidates who are seeking election to the Senate of the Free State

The Executive Council, in the alleged interests of our national status has expressed the intention of setting up a separate Medical Council for the Irish Free State. It certainly seems far fetched to introduce politics into this professional question. Everyone admits the right of the Oireachtas to put an end to the jurisdiction in Ireland of the joint British and Irish body known as the General Medical Council. What we, and the medical profession generally, ask is that the Oireachtas should freely and voluntarily continue to validate this jurisdiction. Once it is admitted that such validation comes from our own legislative assembly, it is hard to see what national claim we are repudiating. We are not asking to hand the educational, ethical and scientific interests of the Irish medical profession over to an outside body. We demand merely that Irish medical men should not be isolated from and placed in an inferior position to their British colleagues but should, in the interests of humanity and efficiency, continue to be associated with them on a status of perfect equality, and that the profession in these islands should be empowered to continue as a professional unit governed by a joint body in which Ireland has more than generous representation. In the history of the General Medical Council there has never been the smallest national discrimination. Such racial or national or political questions never arise and are entirely alien to the purview of the Council. At present most of our medical graduates must seek a livelihood outside the country. The fact may be deplorable but to send them abroad uneducated or with an inferior status is not to provide a remedy. With the emergence of alternative professions with the development of commerce and industry many who now take up medicine will naturally enter for other courses. This readjustment cannot be violently and suddenly effected; it must be left to the course of time. Even if all our present medical students were diverted to Arts or Science, most of them would still have to emigrate to earn their living, whether they leave as teachers and engineers or as doctors makes no difference to the country. Nor must we assume that doctors who emigrate are all a dead loss to the country. Many of them minister to Irish communities in England and Scotland, many of them are centres of Irish influence, some of them return to this country after valuable experience gained abroad and very many of them contribute largely to relatives living in Ireland. What is the alternative to the present system? Probably many of our students will go to Belfast or to Great Britain. Our justly renowned medical schools will become depleted, with the consequent loss to Dublin and Cork not only in money spent in these cities but in gratuitous medical service to the poor. The Irish medical profession, largely deprived of the stimulus of teaching and research, will become isolated and retrograde. If our students enter for other courses they will in any case have mostly to emigrate after graduation so long as the present deficit of professional openings exists. And if they continue as graduates in medicine in any numbers they will be permitted to practise in Great Britain only on sufferance and with an inferior status; they will be quite ineligible for many appointments. They cannot even get on the Colonial Register—the very name is an opprobrium—unless the Irish medical schools are recognized. This last point makes it quite clear that, so far from increasing our national status, the proposed action of the Executive Council will merely degrade and humiliate us. Every single Irish medical school which survives the present shock at all (and some will financially collapse) will be compelled in self-defence to supplicate humbly the British General Medical Council (on which there will then be no Irish representation) to recognize it to examine and inspect it. At present the Council has no such inquisitorial rights of visitation. But when we adopt the 'colonial' status, the Council will have much more authority over our Irish medical schools. So the last condition will be much worse than the first. Such recognition will be a favour to be humbly sued for; it may be withdrawn at any time. The University School of Saskatchewan in Canada for example has just been suspended for midwifery by the General Medical Council. It is plain then that instead of eliminating British control (which does not exist) we shall simply be introducing it in a very drastic form. So much for our national dignity. That our whole system of university and medical education in Ireland needs inquiry and readjustment is willingly conceded. At least one of our university colleges has repeatedly requested the Government to institute such an inquiry. The proposed action is merely a destructive bombshell which will suddenly bring financial ruin to several of our university and medical institutions, one cannot suddenly withdraw the fees of a thousand medical students from financially pressed colleges without producing a crisis. The action of the Government projected without consultation or inquiry is entirely too precipitate and hasty. Such amateur and ill-considered tampering with higher education is to be seriously deprecated. We maintain that the

present system of medical registration and education should be continued, it certainly should not be abolished by a stroke of the pen in the face of all available expert advice, until all the possible reactions and remedies have been thoroughly explored. We therefore request you to sign and return the attached declaration which we have already signed in order that we may have your support and influence in connexion with this vital matter.

The declaration runs as follows:

I, the undersigned hereby express my disagreement with the proposed abolition of the jurisdiction of the joint British and Irish professional body known as the General Medical Council. I consider that such a hasty and premature decision involves serious national educational, humanitarian and medical reactions. I therefore call upon the Executive Council and the Oireachtas to avoid ill-considered action and to validate the jurisdiction of the General Medical Council in the Irish Free State.

STATEMENT BY THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS

In the course of a recent statement Mr R. C. B. Munnell, President of the Royal College of Surgeons in Ireland, says:

'For years to come the profession in the Free State will if the Government do not change their attitude be fully occupied with agitation instead of calmly advancing their scientific work and prospective medical students will depart to seats of learning which can offer them a certain entry to the *Medical Register*. The only reason for this tremendous change with all its loss to the doctors to the students and most of all to the public is that the present system is not in accord with the status and dignity of the Free State. Our Government now says that if it is found impossible to form an Irish Medical Council with an Irish Medical Register, they would rather ask the English Government to admit our doctors to the Colonial List of the *Medical Register*. What does this mean? It means (1) Our representatives on the General Medical Council would cease to exist as members of that body and it would consist exclusively of English, Scottish and Welsh representatives. (2) Our Government would petition the English Government to give our practitioners a place on the list which contains the names of Canadian, Australian and Indians who have taken out their qualification abroad. (3) The English Government would most probably agree to this provided that our universities etc. became subject to inspection by the inspectors appointed by the General Medical Council which would then be purely British. (4) Any physician or surgeon whose name was thus included in the Colonial List would in the case of an accusation of professional misconduct having been lodged against him be summoned to London to be tried by the General Medical Council. There would be no preliminary investigation by an Irish Branch and when he stood before the Council there would be no eight Irish representatives to mitigate his feeling of being a stranger in a strange land. What about the constitutional status and the dignity of the Free State under this arrangement which our Government had said they are perfectly willing to accept rather than submit to a renewal of our present honourable arrangement, which has elevated our profession into the proud position which it now holds? In any case unless the Free State claim recognition as a British Dominion no Free State medical man will be eligible for the Colonial List.'

It may be well to state here the terms of the Medical Act passed in February, 1925, by the Free State Legislature. This Act authorizes the General Medical Council to continue temporarily to exercise authority in respect of medical practitioners in the Irish Free State (Saorstát). It gives to persons registered under the Medical Acts in the Saorstát the same rights, powers, and immunities, and makes them subject to the same obligations as in Ireland before the Saorstát came into existence. The General Medical Council has in relation to persons and matters in the Saorstát, all the old powers, jurisdictions, and authorities, the Branch Council for Ireland similarly retains its powers, the General Council and the Branch Council continue to be constituted and elected as before, and universities and medical corporations in the Saorstát retain their powers of granting diplomas and holding qualifying examinations under the Medical Acts.

We understand that a meeting of medical practitioners, to protest against the decision of the Free State Government to set up a separate *Medical Register*, has been summoned for Tuesday next, September 8th, at 4.30 p.m., at the Royal College of Surgeons, Dublin.

ROYAL MEDICAL BENEVOLENT FUND

At the last meeting of the Committee fifty-four cases were considered and £663 was voted to forty-three applicants. The following is a summary of some of the new cases received.

MRS C. L. R. C. P. 1893 aged 59 married with six children aged 5 to 18 years. The eldest is employed abroad but the rest live at home and attend school. Income from practice and panel dispenser about £230 a year rent and rates £66 per annum. The applicant was taken suddenly ill in July and was operated on for gangrenous bladder. Nursing home fees were paid by his colleague but it was discovered that the wife and family were without means. The Fund lent £10 at once.

Widow aged 58 of L.R.C.P. Edin who was a ship surgeon and died abroad in 1923. The applicant has managed to keep her self and invalid sister on the little money left and by the sale of trinkets and jewellery. This being exhausted a debt was accumulating for board and lodging when a doctor on the committee of the Fund heard of the case and referred her to the Fund. An immediate grant of £5 was made for food. The Professional Classes Aid Council was asked to contribute towards the maintenance of the sister of the applicant who is the unmarried daughter of a solicitor. A vote from it enabled the sister to be sent away to be looked after as she is an invalid and crippled with rheumatoid arthritis. The Guild found a post for the applicant and made a grant towards the debt outstanding for board and lodging. The Fund and Guild and Professional Classes Aid Council are working together to get this sister permanently looked after so that the applicant will be self supporting.

Widow aged 45 of L.R.C.P. Edin who died this year is left with three children aged 6, 9, and 12 who are all at day school. After the practice was sold £500 was left and War Loan purchased. Applicant hopes to augment income by letting apartments. A report from the local branch of the Guild supported the application and the Fund voted £18 towards education and referred the case to the Guild to consider a similar grant.

Widow aged 36 of M.B. who died in 1916. The applicant has been able to support herself and son who is now 9 years of age up to last November when her mother who looked after the boy whilst the applicant was at work died. Help is asked for the child. The Guardians have been applied to and a grant was made by them of 7/6d a week for five weeks. The Fund voted £10 to a local doctor who is interested in the case to be administered for the benefit of the child.

M.R.C.S. Eng. aged 62 who is in practice asked the Fund to help him while getting established. The practice is increasing but he has only £42 in hand. Fund voted £40.

Widow aged 54 of L.M.S.S.A. who practised as a ship surgeon and died suddenly leaving applicant and daughter, aged 17 totally unprovided for. She has been working as a servant but at present is staying with friend. Voted £26 in six monthly instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charles Symonds, K.B.E., M.S., at 11, Chandos Street, Cavendish Square, London, W.1. The Royal Medical Benevolent Fund Guild receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for secondhand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

Medical News.

The Fellowship of Medicine announces that an intensive course in general medicine, surgery, and the various special departments will be held at the Westminster Hospital from September 21st to October 2nd. At the Infants Hospital a two weeks' comprehensive course in diseases of infants commences on September 7th, on which date also at the Seamen's Hospital a five weeks' course in operative surgery begins. In dermatology an afternoon course will be provided at Blackfriars Skin Hospital from September 7th to 19th, with a special demonstration on September 8th. The Royal Westminster Ophthalmic Hospital has arranged a three weeks' course from September 7th. From September 21st to October 3rd the Brompton Hospital provides a special course in the various aspects of pulmonary disease. On four successive Wednesdays, beginning September 23rd, there will be special demonstrations on treatment by electrotherapy at the Royal Fico Hospital. Full particulars of the courses may be obtained from the Secretary at 1, Wimpole Street, W.1.

The Royal Sanitary Institute, 90, Buckingham Palace Road, S.W.1, has arranged a course of lectures and demonstrations for sanitary officers, commencing September 23rd, and for meat and food inspectors, commencing October 2nd.

APPLICATIONS are invited for the post of Director of the Pharmacological Laboratories of the Pharmaceutical Society of Great Britain. The laboratories are being established to meet the requirements of manufacturing chemists and pharmacists who have not the necessary facilities for such biological tests as are to be imposed, under the new Therapeutic Substances Act, in the case of preparations scheduled by Government authority under that Act. The duties of the director will be to supervise and take responsibility for all work of this nature undertaken by the society, and to carry out researches in pharmacology, including the methods of biological assay. It is the aim of the society to promote research of the highest order by giving ample facilities and opportunity, and especially by appointing as many qualified

assistants as may be needed to relieve the director of purely routine work in connexion with the external obligations of his department. The post is not a teaching post, but the society may request the director to give, from time to time, courses of lectures for advanced students of pharmacy. The salary offered is £1,200 per annum, with provision for superannuation under the Educated Universities Scheme. Candidates should be not more than 40 years of age. Every application must be accompanied by three testimonials, and, in addition, by the names of two persons willing to act, in confidence, as referees with regard to the applicant's qualifications for the post. Applications should be sent to the Secretary, Pharmaceutical Society of Great Britain, 17, Bloomsbury Square, W.C.1, before October 5th, 1925.

At a meeting in Geneva of the executive committee and the council of the International Anti Tuberculosis Union, Dr. Theobald Smith, president of the American Association, was nominated president of the union. It was decided that the next international conference should be held at Washington, from September 30th to October 2nd, 1926. The following three questions will be presented for discussion: the part played by contagion in tuberculosis among adults, the anatomical structure of the tubercle from histogenesis to cavity, and tuberculosis and milk. At the scientific meeting of the union held on July 21st Professor Knud Faber of Copenhagen read a paper on the chemotherapy of tuberculosis treated by sanocrysin. A report of the meeting will be published in the next number of the *Bulletin of the International Union*.

The issue of the *Nederlandsch Tydschrift voor Geneeskunde* (the organ of the Dutch Association for the Advancement of Medicine) for August 22nd contains a cordial appreciation by Dr. H. L. W. Droogleever Fortuyn of the new building of the British Medical Association.

The *Bruxelles Medical* is organizing a medical tour to the East, including Syria, Palestine, and Mesopotamia. Further information can be obtained from the secretary of the journal, Dr. R. Bernard, 117, Rue du Trône, Brussels.

The number of students recently enrolled in the medical school for women at Tokyo is 130. There are already 1,200 women doctors in Japan.

The number of medical students enrolled last summer term was 1,126 at Munich and 202 at Königsberg.

The detailed information published in this Educational Number of the *BRITISH MEDICAL JOURNAL* for the benefit of intending students of medicine and newly qualified practitioners has been revised throughout with the co-operation of the deans and secretaries of the medical schools and kindred institutions and of officials in the several Public Services, to all of whom we wish to acknowledge our indebtedness.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE

T. K. MACLACHLAN, M.A., M.B., B.Chir., of Pembroke College, has been elected to the Fearnside Chair of Diseases of the Nervous System. The award is made annually for the encouragement of research in these subjects.

ROYAL COLLEGE OF SURGEONS IN IRELAND

Medical Registration in the Free State

The following resolution was unanimously adopted at a special meeting of the President, Vice President, and Council of the Royal College of Surgeons:

That we desire to express our high appreciation of the conduct of our President (Mr. R. C. B. Maunsell) in the recent controversy, and our confidence in his defence of the interests of our College.

The Council then considered the whole situation, and also suggestions from various sources that it should make a political matter of it. The Council decided that as the medical profession has never interfered in any way in politics it was determined to fight this by educating public opinion and only thus influencing politicians. As a beginning of the education of the public it has decided to hold a meeting of medical practitioners on September 8th in the Examination Hall of the College (see page 456).

DENTAL EXAMINATIONS

An Addendum to Minutes of the General Medical Council for 1925 has been issued. It contains a report by the Dental Education and Examination Committee on the inspection of the qualifying examinations in dentistry and dental surgery that were held during the years 1913 and 1924. The inspector, Mr. J. Howard Munnery, contributes also a general account of the final examinations in dentistry of the licensing bodies of the United Kingdom and Ireland, and individual reports of fifteen universities and training centres are appended.

¹ Addendum to Minutes of General Medical Council for 1925. London: Constable and Co. Ltd. 1925. (Extra post 8vo pp. 275. 7s. 6d. net.)

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W C 1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring PEPERINIS of their article published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1 on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the JOURNAL should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are MUSFUM 9561, 9667, 9563, and 9564 (internal exchange four lines).

The TELEGRAPHIC ADDRESSES are EDITOR of the British Medical Journal Articology Westcent, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc) Articulate Westcent London.

MEDICAL SECRETARY Mediscera Westcent London.

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus Dublin* telephone 4737 Dublin) and of the Scottish Office 6, Drumshugh Gardens, Edinburgh (telegrams *Association Edinburgh* telephone 4361 Central).

QUERIES AND ANSWERS

DIVERS' PARALYSIS

Dr H. E. S. STIVEN, P.M.O. Government Hospital Port Said, Egypt, asks for information about divers' paralysis. He has met with three cases—one in a Greek sponge diver and two in Japanese divers working in 40 fathoms (240 feet) of water; they did not wear divers' dress, but had a mask fixed over the face and used compressed air for respiration. Of the Japanese the first had been down for forty-five minutes and had come struggling up to the surface, not following the British naval practice of divers (in diving dress) to rest twenty minutes half way. The second Japanese was down for fifteen minutes, about ten minutes after coming to the surface he lost consciousness; he was admitted to the hospital about forty-eight hours afterwards with a temperature of 106° F. and complete paralysis from the waist down. He died six hours later. Dr Stiven states that he has read that the symptoms are due to bubbles of nitrogen released from the blood when the pressure is removed but does not understand why death may ensue so long afterwards.

* It is fully established that the cause of divers' paralysis or caisson disease is the liberation of bubbles of nitrogen from the blood and tissues during decompression. The severity of the symptoms depends, first on the degree of saturation with nitrogen and therefore upon the depth reached and the length of time spent below and secondly, on the rate of decompression. Sudden decompression from the great depth of 40 fathoms must be extremely dangerous. Whether the symptoms are immediately fatal or not depends upon the situation reached by the nitrogen emboli but as a rule these are most abundant in the lower part of the thoracic cord hence the characteristic paraplegia. Immediate relief is generally obtained even from severe symptoms by recompression if practised at once. It is carried out in bridge building by having a compressed air chamber available known as a "medical air lock." Such a chamber ought also to be provided on ships engaged in deep salvage. Accounts of this disease may be found in the textbooks of medicine by Osler, Taylor, and Price.

INCOME TAX

Purchase of Share in Partnership

W. A. J. took over, as from August 1st, 1924 the half share in a practice. What is his position as regards the 1924-25 assessment?

* He cannot introduce his previous earnings into the computation of the average for assessment, which must be based on the earnings or profits of the practice. Assuming that the average earnings of the practice in the three years 1921, 1922 and 1923 were £x, he must account for the tax due in respect of eight twelfths of one half £x—once third £x—eight twelfths being the proportion of the year 1924-25 during which he was entitled to half the profits of the practice. If it should be found that the profits have fallen short of the sum assessed from some specific cause since or by reason of the change in proprietorship of the practice an adjustment can be obtained by way of repayment or otherwise at the end of the financial year. There is no fixed scale for depreciation of cars, but we believe that 15 per cent of the net cost is a common basis.

Income from Abroad

"X Z" has recently come to this country for the combined purposes of a holiday and postgraduate study. He is in possession of an income of £600 a year from Australian property but is expending £500 a year while temporarily residing here.

* Our correspondent is liable to account for tax on an investment income of (say) £600 per annum; he cannot deduct the Australian tax in computing the amount of that income but is entitled to an allowance for the double tax. Apart from that relief which would depend partly on the amount of Australian tax paid on the income, the amount of tax payable for 1924-25 would be approximately £40.

Cash Receipts

"J. A. S." has been in the same practice since 1903, and so far has made his returns on the basis of the cash receipts and payments of each year. He has now been requested to supply accounts showing the bookings and expenses incurred, whether paid or not.

* The request is proper in circumstances in which the cash receipts are expanding or contracting so rapidly that the cash receipts do not properly represent the value of the bookings, but if there are no such circumstances we see no reason why the existing basis, which has been in operation for a considerable length of time, should be discarded. It is very much more convenient for both parties, and in the long run should produce the same result. We suggest that "J. A. S." should press the Inspector of Taxes to say why in his case he is not prepared to accept the usual basis of assessment. A claim for depreciation of motor car may be made, the appropriate amount being deducted from the average assessments.

LETTERS, NOTES, ETC.

THE FUTURE OF CHIROPRACTIC

UNDER this heading the *Journal of the American Medical Association* recently (August 8th p. 449) published an account of the present position of "chiropractic" in the United States. From this it appears that in three States statutes have been passed to regularize the position of the chiropractic group. In Mexico (1921) chiropractors were authorized to diagnose and treat all infirmities provided they did not use drugs or perform surgical operations. In California a chiropractic license was established (1922) authorizing the holder to practise chiropractic in the State as taught in chiropractic schools or colleges. In the State of Maine (1923) a statute was passed following, in a general way, the California Act. It entitled the holder to practise "chiropractic" in any country in this State in all its branches as taught and practised by the recognized schools and colleges of chiropractic but it shall not authorize the holder to practise obstetrics so far as the same relates to parturition nor to administer drugs or perform surgical operations with the use of instruments except as now allowed by statute. In concluding its article our contemporary writes: "The first annual report of the Board of Chiropractic Examiners of the State of California, 1923-1924, closes the fact that any chiropractic school in order to be in good standing and to have its graduates admitted to examination in California must include in its curriculum the study of elementary chemistry and toxicology 100 hours, bacteriology, 100 hours, and obstetrics and gynecology, 100 hours. An 'hour' is defined as forty-five minutes or the equivalent thereof. Once chemistry, toxicology, bacteriology, obstetrics and gynecology are established in the chiropractic curriculum pharmacology, therapeutics and surgery will promptly follow. Then will follow the era of chiropractic, echom, the present era of osteopathy. For the substantially unrestricted right to enter the practice of medicine and surgery, by its own carefully planned back door."

A BREAST FEEDING CAMPAIGN IN SWITZERLAND

A SWISS medical woman, Dr Imboden-Kaiser, has published in the *Schweizerische medizinische Wochenschrift* of June 25th statistics of an educational campaign in regard to the infant welfare centre. She was able in the course of ten years to raise the frequency of breast-feeding among the mothers from 53 to 86 per cent. The average duration of suckling among the mothers who gave breast was raised from 2 to 2.7 months and among all the infants including those who were not suckled, this average was raised from 1.1 to 2.3 months. These results were achieved, not by giving drugs, nor by feeding the mothers better, but by an educational campaign each mother being taught exactly what to do and how to avoid the many errors which lead to a failing milk supply. One of the measures advocated in cases of a deficient milk supply (as shown by inadequate gain of weight of the infant) was to continue every one of the six breast meals and to supplement the last two or four by artificial feeding.

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 71, 72, 73, 76 and 77 of our advertisement columns and advertisements as to partnerships, assistantships and locumtenencies at pages 74 and 75.

A short summary of vacant posts notified in the advertisement columns appears at page 460.

The British Medical Association:

ITS AIMS, WORK, AND CONSTITUTION

The British Medical Association was founded in 1832 to promote the medical and allied sciences, to maintain the honour and interests of the profession, and to foster a feeling of friendship among its members. To attain these objects it holds periodical meetings for the discussion both of medical and scientific subjects and of professional affairs, it publishes the *BRITISH MEDICAL JOURNAL*, it maintains a reference and lending library, it has instituted lectures, and scholarships and grants for research. It thus concerns itself with every side of medical work—science, clinical medicine, public health, and the material interests of professional life. The British Medical Association, with a membership now of more than 30,000, is the oldest, largest, and most powerful British organization devoted to the welfare of the medical profession. It has recently acquired a fine building in Tavistock Square, London, for its headquarters, providing ample accommodation for immediate needs and space for future developments. These new premises, designed by Sir Edwin Lutyens, R.A., were formally opened by His Majesty the King, accompanied by the Queen, on July 13th last, and the beautiful wrought-iron gates erected as a memorial to the 574 members who fell in the war, by which the quadrangle is completed, were dedicated on that occasion by the Archbishop of Canterbury. A full description of the new buildings and of the opening ceremony, with many illustrations, appeared in the *BRITISH MEDICAL JOURNAL* of July 18th. The need for larger accommodation had become insistent owing to the remarkable growth in the central work of the Association during recent years, which had far outstripped the capacity of the premises at 429, Strand.

Constitution and Administration

The Association has Branches and Divisions throughout Great Britain and Ireland, and also in the Dominions, Colonies, and Dependencies. The Divisions are arranged territorially, and number in all, 283. For certain purposes of administration or of scientific and clinical work, the Divisions are combined into 95 Branches. Members of Divisions elect representatives on the Branch Councils and also a member or members of the Representative Body, which is the governing body of the Association and determines its policy.

The Council is the executive of the Association. It is elected partly by the Divisions and Branches and partly by the Representative Body, and includes representatives of the Navy, Air Force, Army, and Indian Medical Services elected by the Representative Body. The Representative Body and Council elect standing committees to take charge of different subjects. Among these may be mentioned the Science, Medico-Political, Ethical, Hospitals, Public Health, and Naval and Military Committees. There are Committees also for the Dominions, Scotland, Ireland, and Wales, and for the working machinery of the Association such as the Organization, Finance, and Journal Committees. The Insurance Acts Committee, elected partly by the Association and partly by insurance medical practitioners, is financed by the Association, it is the recognized executive and mouthpiece of the insurance practitioners of Great Britain.

Privileges of Members

A member of the Association has the right—

- 1 To attend the annual and other general meetings of the Association and the meetings of the Division and Branch to which he or she belongs.
- 2 To take part by personal vote (or in some Divisions by voting paper) in the election of the representative of his or her Division in the Representative Body and also in the election of members of the Council.
- 3 To receive by post the *BRITISH MEDICAL JOURNAL*, published weekly, which gives a full record with commentary of progress in clinical and scientific medicine and of medico-political affairs throughout the British Empire.
- 4 To receive the help and advice of the central office in any professional difficulty.
- 5 To use the Library as a reading room and to borrow current medical or scientific books on payment of postage. Besides modern works and periodical medical literature—foreign as well as English—the library contains many books of historic interest.

The full benefits of the Association can only be secured by the co-operation of large numbers of the medical profession for the greater the membership and the funds the more

efficient and influential the organization. The Association during the past ninety-three years has been the direct means of benefiting every class of medical men and medical women. In asking for new members it looks not only to the older practitioners but also to those recently qualified. To these a generous concession is made as regards subscription, and there is a special claim to their recognition of the work of the Association in improving the conditions under which they may hold appointments in the public services or in civil life. The Association's work for

COURT OF HONOUR, FROM SOUTH WEST ANGLE

[Country Life]

the services is well known. It considers itself to be in a special sense the guardian of the interests of those members of the profession who by reason of their position are precluded from taking common action.

Subscriptions and Applications for Membership

The ordinary subscription to the British Medical Association is 3 guineas a year for members resident in the British Isles, but this is subject to various exceptions. Thus, newly qualified practitioners elected within two years of registration pay half this sum up to the end of the fourth year after registration, medical officers on the active list of the R.N., R.A.F., R.A.M.C. (Regular), and I.M.S. pay 2 guineas; concessions are made also to members (in the British Isles) of forty years' standing, to members of ten years' standing who have retired from practice, to medical married couples residing together, and to whole-time teachers and research workers. The ordinary subscription for members living abroad is 1½ guineas, but some Branches have special local subscriptions. A member elected after June 30th in any year pays for that year one-half the current annual subscription.

All duly qualified British medical practitioners are eligible for election. Full particulars can be obtained from the Medical Secretary, British Medical Association House, Tavistock Square, London W.C.1, the Scottish Medical Secretary, 6, Drumshugh Gardens, Edinburgh, or the Irish Medical Secretary, 16, South Frederick Street, Dublin.

British Medical Association.

PROCEEDINGS OF SECTIONS AT THE ANNUAL MEETING, BATH, 1925

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE

SIR MAURICE CRAIG, CBE, MD, FRCP, President

DISCUSSION ON CAUSATION AND SYMPTOMATOLOGY OF MULTIPLE NEURITIS

OPENING PAPER

T. GRAINGER STEWART, MD EDIN, FRCP LOND,
Physician Out-patients National Hospital for the Paralyzed and Epileptic Queen Square

When opening a discussion it is prudent to formulate some definition of the subject. We must first agree as to what conditions or diseases we will include under the term "multiple neuritis." The honorary secretaries have not furnished me with a definition, and I have sometimes regretted that I did not ask for one. I feel, however, that we will all find ourselves on more or less common ground if we take a wide view and define multiple neuritis in clinical terms as a condition, rather than as a definite morbid entity, which a strict application of the term would entail.

Definition.—I propose to include under the term "multiple neuritis" all cases in which as the result of a general cause—toxic, infectious, or metabolic—the symptoms present point to a more or less simultaneous affection of many of the peripheral nerves, or of their associated peripheral neurones, as manifested by disturbance or abolition of their functions. By thus defining multiple neuritis I exclude all cases of neuritis directly due to local traumatism or compression but I do not exclude those in which the neuritis arises as the result of the general action of a toxin, developed locally in connexion with a local lesion. Further, it permits us to include cases in which the symptoms point to an involvement of the peripheral neurones rather than of the peripheral nerves proper. The expediency for widening the definition becomes apparent when we consider the difficulty there is in determining in many cases whether the initial changes occur in the nerves themselves or in their central connexions.

Classification.—It is quite impracticable in the present state of our knowledge to attempt to classify multiple neuritis on any other than an etiological basis for although the symptoms and the clinical picture in certain forms of multiple neuritis are distinctive yet in the majority of cases no clinical differentiation is possible. Nor can we adopt a pathological classification, as the morbid changes present exhibit certain general features common to all forms, and the discrimination between the finer changes has not yet progressed sufficiently to afford a basis for classification.

CLASSIFICATION

A *Exogenous Poisons*—Lead arsenic mercury etc Alcohol carbon monoxide carbon bisulphide trinitrotoluene sulphonal trional chloral chloroform anilin Serum etc etc with multiple neuritis

B *Endogenous Toxins*

- 1 Metabolic diabetes beriberi bromatophyphimie during pregnancy
- 2 Cachectic malignant disease acute chronic anaemia etc
- 3 Infective
 - (1) In association with many acute infective fevers as an occasional feature typhoid paratyphoid scarlet fever etc tubercle, syphilis gonorrhoea septicaemia, puerperal
 - (2) In certain epidemic—for example influenza as a predominant feature
 - (3) In infective diseases in which the neuritis is an essential part of the clinical picture—for example uveo parotitic paralysis pink disease

(4) In organismal infections in which the toxin developed has a special affinity for the nervous system—for example diphtheria

(5) In acute subacute or chronic infectious whose incidence is chiefly on the nervous system acute toxic polyn neuritis acute febrile polyn neuritis acute infective polyn neuritis Landry's paralysis recurrent multiple neuritis

C *Multiple Neuritis of Obscure Origin*—Rheumatic from exposure to cold

D *Local Infections of Nerve*—Leprosy Interstitial hypertrophic neuritis (1) juvenile (Dejerine and Sottas) (2) adult (Dide and Courjon)

Pathogenesis

An inquiry into the causation of multiple neuritis involves the consideration of the following points

- 1 The nature of the poison or toxin
- 2 How it is produced
- 3 How it gains entrance into the body
- 4 How it is absorbed within the body
- 5 The effect it has on the tissues and organs of the body generally as regards function and structure
- 6 Its effect on the nervous system
- 7 The paths by which it gains entrance into the nervous system

Before referring in detail to the various types set out in this classification let us consider briefly what are the principal factors which determine the mode of onset and the distribution of the symptoms in multiple neuritis. The two factors which determine the mode of onset and the distribution of the symptoms in multiple neuritis are (1) the selective action of the poison, (2) the distribution of the poison within the nervous system.

1 *Selective Action.*—We know that the nervous system has the property of fixing certain toxins and poisons, and that this depends upon a special chemical affinity between the toxin and various chemical constituents of the nervous system. The toxins of tubercle and diphtheria, for example, become fixed in the nervous system, either *in vivo* or *in vitro*, and this is apparently due to their forming a complex with the phosphorylated lipoids. It has also been demonstrated that the violence of these toxins is increased as a result of this fixation. The toxin of tetanus also is fixed by the nervous system, but in this instance the fixation is brought about by the protein elements and apparently exercises some neutralizing action on the toxin. These observations serve to show how varied may be the chemical processes underlying the selective action of any poison, and may also in part explain the fulminating character of the symptoms occasionally seen in the acute forms of multiple polyn neuritis.

2 *The Distribution of the Toxin.*—This will, of course be influenced by the selective factor, but its incidence will be determined in the first place by the paths by which the toxin reaches the nervous system. We know that toxins and bacteria may enter the central nervous system by two channels (1) by way of the blood, (2) by way of the nerves (neural lymphatics). I need only say that their passage by the latter path has been demonstrated by many pathological and experimental investigations. Orr and Rows showed conclusively that toxins and bacteria could pass into the central nervous system by way of the perineural lymphatics and spread in the lymph spaces of the perirachnoid and in those of the substance of the cord. The effect was to produce an inflammatory reaction in the connective tissue elements, chromatolysis in the nerve cells and myelin degeneration in the spinal roots, limited almost entirely to the intramedullary course of the nerves from the point where the neurolemma sheath is lost. Greenfield and Carmichael state that there is evidence in cases of interstitial neuritis of the passage of inflammatory exudate from the nerves into the subarachnoid space. Feale and Embleton have made special investigations as to the paths by which tetanus toxin spreads to the central nervous system. They confirm the view held by Marie and Morry and Mayer and Pansom that it can ascend by way of the axo-cylinders of the motor roots, but hold that it passes chiefly by way of the perineural lymphatics of the anterior roots. Lastly we must always bear in mind that the distribution of the toxin may be prevented or modified by the resistance offered by the natural defences of the body.

I now pass to the consideration of the first group of our classification—exogenous poisons

EXOGENOUS POISONS

Our knowledge regarding this group is fairly complete, not only as regards the poisons themselves and the chemical combinations in which they are most dangerous, but more especially as to the channels by which they enter the body. For this we are indebted chiefly to the labors of industrial toxicologists. The application of regulations based on the result of their work has materially reduced the number of cases of industrial poisoning, lowered the mortality, and lessened the disablement. I will refer only briefly to three varieties of multiple neuritis which fall into this group—namely, alcohol, lead, and arsenic.

ALCOHOLIC NEURITIS

Alcoholic neuritis, formerly the commonest variety of multiple neuritis met with in this country is now comparatively rare.

Etiology

It occurs most frequently in chronic alcoholics, especially in persistent and secret drinkers and those addicted to spirit drinking. Women are more affected than men. It is often associated with obvious disorders of the digestive, respiratory, cardiac, and renal systems.

In Scotland—a whisky-drinking country—alcoholic neuritis and alcoholic cirrhosis of the liver are uncommon. This would appear to contravene the statement that spirit drinkers suffer more than beer drinkers, but the explanation lies in the fact that drinking in Scotland is mostly confined to Saturday nights and the week-end, and that frequently most of the alcohol is ejected before it is absorbed into the blood. In England, where drunkenness is less obtrusive, alcoholic neuritis and cirrhosis of the liver are more common. Statistics from the National Hospital, Queen Square, however, show that the great majority of cases of alcoholic neuritis admitted to the hospital were due, not to drinking beer, but to the continued abuse of spirits—gin, whisky, and brandy. In many instances the fact that the patients were in the habit of taking alcohol was only discovered when the neuritis was diagnosed. In beer-drinking countries neuritis is usually only one of many obvious signs that the patient has for long been seeking himself with beer.

Experimental work upon the absorption and elimination of alcohol by the body throws light upon the etiology of multiple neuritis.

Alcohol is rapidly absorbed from the stomach and small intestines, in from half an hour to two hours, and undergoes no change in the process. Absorption takes place more rapidly if the alcohol is in strong solution, or when the stomach is empty, more slowly if it is diluted or taken with food. It passes directly into the blood stream, and therefore the amount circulating in the blood varies according to the quantity taken. It is more or less evenly distributed to the tissues of the body, and its presence has been detected in the cerebro spinal fluid after its administration by the mouth.

Only a small proportion of the alcohol is excreted as such by the kidneys and lungs—generally about 2 per cent, and never more than 10 per cent. The remainder is eliminated as water and carbonic acid gas, these changes being effected by the oxidation of the alcohol in the body tissues. Thus, after taking a dose of alcohol, there is a period in which it reaches its maximum concentration in the blood, after which it diminishes, but the rate of diminution is not influenced by the size of the dose. It follows that the larger the dose the longer will be the time required for its elimination. Mellanby has calculated, as a result of experiments in man, that 10 ccm of alcohol is oxidized in an hour. He points out that until elimination has taken place the absorption of even a small quantity, which otherwise would have had no ill effects, may immediately induce intoxication.

If we take all these facts into consideration we must agree that the most potent factor is the continued presence of alcohol in the blood. Whether the neuritis results directly from the action of the alcohol on the nerves or indirectly from the associated action of other toxins and

a lowered state of nutrition, is a debatable question, but personally I incline to the opinion that the neuritis is primarily due to the alcohol.

Clinical

Precursory signs may be present for a long time before the onset of definite paralysis. These include numbness, tingling, and paresthesia in the feet and fingers, pains in the limbs, especially at night, cramps in the muscles, muscular tenderness, and hyperaesthesia of the soles. There may be tremor and clumsiness in the finer movements, and even transient weakness of all four extremities. If the cause of these symptoms is recognized and removed recovery may take place without any further developments, if not, the symptoms progress and the patient develops the typical signs and symptoms.

Of the various clinical types which have been described I will only refer to two: (1) a pseudo tabetic sensory type, in which pain is the prominent symptom and is associated with an acute ataxia of the lower limbs due to loss of the sense of position at a stage when the patient is still able to use his legs, (2) an acute type, usually fatal, in which the paralysis is severe, affecting not only the limb, but the heart and other muscles, and occasionally the cranial nerves.

In all cases of alcoholic neuritis certain characteristic features will be noticed:

- (1) The severity of the pain and sensory disturbances.
- (2) The acute tenderness of the nerves and muscles on account of which the patient may cease to use his limbs before there is any definite paralysis.
- (3) The tendency for the lower extremities to be affected earlier and more severely than the upper.
- (4) The peripheral distribution of the symptom with weakness predominating in the extensor muscles.
- (5) The rapid onset of contraction and deformities due to fibrosis affecting the muscles, tendon sheaths and fibrous tissue generally.
- (6) The occurrence of mental changes, often associated with a more or less typical psychosis.

The basis of this psychosis, which Korsakoff described in 1837, is an amnesia for recent events combined with a disorientation in space and time. The effect of this retrograde amnesia is that the patient forgets from one minute to another what he has said or read, and he may continue to repeat the same question or statement over and over again. Vague memories of the past persisting in his disoriented mind are woven into the present, he cannot distinguish fantasy from reality. This leads to the third characteristic of the psychosis—fabulation. In this stage the patient will maintain a conversation full of plausible fictions which his imagination and surroundings may suggest.

LEAD NEURITIS

Lead palsy is only one of the manifestations of lead poisoning, and although it generally arises during the course of a chronic intoxication it sometimes supervenes on an acute. A number of cases have been reported in which the paralysis has developed months, or even years, after the patient has ceased to be exposed to the risk of infection.

Lead poisoning results from ingestion of the poison itself or of food or water contaminated with lead, from inhalation of lead in the form of fumes or dust, or, more rarely, from absorption through the skin. Oliver considers that the greatest amount is absorbed by the digestive tract, Legge and Gordby by the lungs. The hydrochloric acid of the gastric juice is a potent solvent, and may convert the lead into a chloride, in which form it is supposed to be absorbed into the blood stream. In the lungs it is subjected to the action of moisture and heat. The fluids secreted are all alkaline, and, as carbonic acid gas is present, it is conceivable that the lead is changed from lead carbonate into bicarbonate, dissolved and absorbed. It is excreted in the faeces, by the kidneys, and by the skin.

Oliver points out that lead chloride, when in intimate contact with proteins, combines to form albuminate, a rather insoluble substance, and that a considerable amount of protection may be afforded by insisting on those exposed to the risk of poisoning taking good and regular meals.

Symptomatology

The special features of lead neuritis are

(1) The absence of sensory symptoms—the only subjective sensations being cramps in the muscles. Examination fails in most cases to reveal any sensory loss and where such loss has been found it has been patchy and indefinite.

(2) There is never any tenderness of the nerve trunks.

(3) The palsy generally affects the upper extremities rather than the lower, is bilateral and segmental, and is often localized in a special manner to certain groups of muscles.

(4) Associated with the palsy there is evidence of lead intoxication either in a previous history of headache, gastric disorder, constipation, colic, or the presence of uræmia—pale, yellow tinted complexion, a lead line in the gums, pigmentation of the mucous membranes of the mouth, enlargement of the parotids and the characteristic renal and vascular changes.

Various types have been described according to the distribution of the palsy.

The commonest is the *radial type* (Remak)—seventh cervical—in which the extensors of the wrist and fingers, the extensors and long abductor of the thumb are paralysed, causing drop-wrist. The supinator longus muscle, innervated from the fifth cervical root, generally escapes—a point which serves to distinguish lead palsy from a simple musculo-spiral paralysis. The extensor communis is first affected, followed by paralysis of the extensors of the index and little fingers, and of the thumb and wrist. Associated with this there may be paralysis of the anterior tibial and peroneal muscles, causing foot-drop and steppage gait. The *tibialis anticus* muscle, like the supinator longus in the upper extremity, is seldom affected.

The *Asian-Duchenne type*—eighth cervical and first dorsal—is characterized by weakness and wasting of the small muscles of the hand. As a rule the atrophy precedes any definite loss of power, the onset is slow and fibrillation is often present. In the *Duchenne-Erb type*—fifth and sixth cervical—which is not common, the muscles affected are the deltoid, biceps, brachialis anticus, and supinator longus, and occasionally some of the shoulder girdle muscles.

In the *progressive muscular atrophy type*, which clinically resembles progressive muscular atrophy, there is a progressive degeneration of the muscles. Weakness and wasting may first be noticed in any of the muscle groups commonly affected in lead paralysis, but tends to spread and involve, not only the muscles of the upper and lower extremities, but sometimes those of the neck and trunk. It is of interest to note that quite a number of cases have been reported in which, in addition to the affection of the upper motor neurones, there has been involvement of the pyramidal system.

The clinical picture in lead palsy points to an affection primarily of the lower motor neurone—both cells and fibres—and its segmental or radicular distribution to a neuronic rather than to a neuritic affection.

ARSENICAL NEURITIS

Arsenical neuritis is rarely met with, but has always attracted public interest, as arsenic has frequently been administered with criminal intent. It was known as a criminal poison to the Chinese over a thousand years B.C., and was the principal ingredient of the celebrated aqua tofani, a notorious poison in the fifteenth and sixteenth centuries. Arsenic may be inhaled or ingested, and may be found in the hair and epidermis many months after it has disappeared from the urine and faeces. Its toxic action is due to the arsenious acid ion, which has an affinity for the neurokeratin of the nerve sheaths. Arsenical compounds from which this ion is only slowly dissociated are therefore less toxic, and for this reason the organic arsenic compounds do not often cause typical poisoning.

Etiology

Arsenical neuritis may arise as a result of acute or chronic poisoning, accidental or intentional. It occurred in epidemic form in Manchester in 1900 as a result of the consumption of beer brewed with glucose which had been contaminated with arsenic. Sporadic cases have been reported from time to time in which the patients have been poisoned by inhaling or absorbing arsenic from wall papers or articles impregnated with it. Its occurrence in industrial occupations is rare since its use as a pigment has been restricted.

Apart from its occurrence as the result of acute poisoning, accidental or intentional, arsenical neuritis may arise from the prolonged use of the drug in the treatment of such diseases as cancer and the severe anaemias. Cases have also occurred during the treatment of parasitical diseases with the organic arsenic compounds, *arsol* (sodium arsinate) has occasionally caused ichthyoid neuritis and optic atrophy.

Clinical

In arsenical neuritis all four extremities are commonly affected. The sensory disturbances are severe, pain is a prominent feature, and the muscles and nerves are always exquisitely tender on pressure. On the motor side the paralysis not only affects the extensor muscles, causing wrist-drop and foot-drop, but also the small muscles of the hands and feet. In severe cases the calf muscles and the quadriceps extensor may also be affected. Recovery is always slow, and wasting may be extreme.

The trophic changes are outstanding. The finger pads are wasted, the nails become brittle and brittle shaped and striated longitudinally or transversely, the hair falls out, there is hyperkeratosis of the skin of the soles and palms, and various skin eruptions may appear. Most striking, however, is the occurrence of pigmentation due to the deposition of an organic pigment in the deeper layers of the corium. It is most marked in those areas naturally pigmented and where the clothing comes into close contact with the body. Over the lower chest and abdomen the skin has a mottled appearance, and within the pigmented areas there are small patches in which the skin looks whiter than normal. General manifestations of arsenical poisoning are often present, such as a gradual loss of flesh and a state of malnutrition, signs of coma, and severe gastro-intestinal irritation.

ENDOGENOUS POISONS

METABOLIC GROUP

Diabetes

In diabetes mellitus evidence of affection of the nervous system, more especially of the sensory functions, is present in about 50 per cent of cases. The patient may come complaining of symptoms of multiple neuritis, which draw attention to the diabetes, or the systematic examination of a diabetic patient may reveal a co-existent neuritis. The neuritis in diabetes mellitus may be multiple or local.

In the multiple form the prognosis of the neuritis is essentially that of the diabetes. There is no evidence to show that the severity of the neuritis is proportional to the degree of hyperglycaemia, but it would appear to be influenced to some extent by the duration of the disease. Sensory symptoms predominate. The patient complains chiefly of pains, often deep-seated and invariably associated with tenderness of the muscles. Examination reveals little disturbance of the cutaneous sensibility, but grave defects in the deeper forms of sensation. Williamson has drawn attention to the loss of vibration sense, and regards its early disappearance as a point of some diagnostic significance. The loss of sense of position may be extreme, and gives rise to a clinical picture more closely simulating tabes than that seen in any other form of multiple neuritis. It is rare to find complete paralysis, although definite weakness is easily demonstrable. The disability of the patient may be much greater than is accounted for by the paralysis, partly because of the muscular tenderness, and partly because of the associated uræmia. The lower extremities are more often affected than the upper, and the earliest sign may be the loss of the ankle-jerk, which usually precedes the diminution or disappearance of the knee-jerk.

Local neuritis is of common occurrence in cases of diabetes, and most frequently affects one or both external popliteal nerves. As a rule it is of a benign type, and I have seen many cases in which complete recovery has taken place. I have seen in long-standing cases of diabetes with arterio-sclerosis a sudden onset of sciatic paralysis with pain and tenderness of the muscles, complete sensory loss, and abolition of the ankle-jerk. This condition is always monoplegic in distribution, and recovery of function rarely occurs. The wasting is extreme, and the case may be complicated by the development of trophic sores. It is not due to a simple neuritis, as *post-mortem* examination of

some of these cases has revealed a thrombosis of the main arterial supply of the affected nerve.

Trophic changes are frequently associated with diabetic multiple neuritis, they may, however, in part be due to the diabetic ulcer, but differing in that they are painful, and localized patches of gangrene may occur at any time, and are occasionally the earliest manifestations.

Beri-beri

This disease is characterized by the onset of the typical signs of multiple neuritis, and occurs in two forms—the dry, in which there is a simple multiple neuritis, and the wet, in which there is an associated anaemia and exudation into the serous cavities. Death may occur suddenly from cardiac failure.

This disease occurs in epidemic form in certain tropical countries where the staple food consists of rice or wheat, and occasionally on sailing ships supplied with canned food. It is now known that the cause of the disease is the absence of an essential vitamin—the antineuritic or water-soluble B vitamin. This vitamin is present in the germ and aleurone layers of rice and wheat, and in less degree in fresh food; it is destroyed at a temperature of 120° C.

Where epidemics have occurred it has been found that the vitamin has been destroyed either by the polishing of the rice, the over-milling of the wheat, or by excessive heat in the canning process, if the diet is rectified complete recovery will take place.

INFECTIVE GROUP

The association of multiple neuritis with various known forms of infectious disease, its occurrence as the sequel to febrile disturbances of unknown origin, and, lastly, its appearance as the main clinical expression of an acute infectious illness, have given a special stimulus to the investigation of what may be termed the acute toxic groups of multiple neuritis.

We find multiple neuritis occurring in association with well-known varieties of infectious diseases—for example, typhoid—either during the course of the illness or supervening upon it. Although these cases are not uncommon they are relatively extremely rare, and must be attributed to an exceptional and adventitious invasion of the nervous system rather than to any selective action on the part of the organism or toxin.

Influenza does not usually cause multiple neuritis, but certain epidemics of this disease have been notable for the constancy with which the nervous system has been involved, and one of the commonest manifestations of this has been the occurrence of multiple neuritis. Are we to regard this as being due to a special neuro-selective quality in the variety of the organism or to the special incidence of the disease affording an easier path for the invasion of the nervous system by the organism or toxin?

Multiple neuritis occurs in certain infective diseases, in which it forms an essential part of the clinical picture, as examples of this the following may be mentioned.

Uveo-parotitic Paralysis

This is a rare disease, in which an inflammatory process of the anterior segments of the uvea and of the parotids is associated with a neuritis affecting the facial nerves, occasionally other cranial nerves, and rarely the nerves of the limbs and trunk. It was first described by Heerfordt in 1909. Cases have been reported in this country by Feilding and Viner, Mackay, Biewerton, and McBride. It belongs to the toxic infective group, and is more common than would appear from the literature.

Erythroedema Polynucleitis

Cases of this disease have been reported in Australia (Swift), in this country (Still and Gamod, and Patterson and Greenfield), and in North America. It affects children between the ages of 4 months and 3½ years. Two to three weeks after an initial fever with catarrhal symptoms the child becomes miserable, irritable, and sleepless. A diffuse erythematous rash appears. The hands, feet, cheeks, nose, and forehead become red and swollen, but do not pit on pressure. There is excessive sweating and extreme irritability of the skin. The hair drops out,

and the nails become soft and may fall off. The muscles become tender, the deep reflexes are abolished, and there is general weakness and hypotonia without actual paralysis. The jaw drops and the head may droop. The patient lies crouching and curled up in bed. Photophobia may be present. There is extreme anorexia which may cause death, but, generally speaking, the mortality is low.

Diphtheria

Diphtheria provides us with another example of multiple neuritis occurring in association with an infectious disease, but here we have an organismal infection developing its local lesion on a surface of the body, and at the same time evolving a toxin which has a selective action on the nervous system. Paralysis occurs in about 20 per cent of cases of diphtheria, and the frequency and severity of the paralyses in faucial diphtheria, as J. D. Rolleston has shown, is always in direct proportion to the severity of the local lesion. Its incidence in 800 severe cases was 48.1 per cent, in 498 moderate cases 13.6 per cent, and in 1,899 mild cases 2.4 per cent.

Experimental proof that early injection of antitoxin can prevent paralysis has been given by Rosenau and Anderson. From statistics furnished by Rolleston and others it would appear that in those cases in which the bacilli were destroyed early no multiple neuritis occurred. It is only when the local lesion has been missed or neglected that severe paralysis follows a mild infection. The association between diphtheritic infection and subsequent paralysis was pointed out by Mangin in his Paris thesis of 1854, and later he published an important work on diphtheritic paralysis, in which he described an instance of paralysis following cutaneous diphtheria.

Diphtheritic paralysis may be local, affecting parts related anatomically by nervous connections to the site of infection, or general and widespread, affecting parts not in direct nervous connexion with the site of the diphtheritic lesion. Its most characteristic manifestation, however, is the paralysis of accommodation, which is rarely absent in cases with local paralysis, whether of faucial or cutaneous origin, and occurs quite independently of the general paralysis. The paralysis of accommodation, therefore, may be regarded as the specific sign of diphtheritic paralysis.

Local Paralysis.—Instances of local paralysis are familiar to all, the most common example being the palatal palsy in faucial cases. Guérin advanced the view that the toxin spreads to the central nervous system by an "ascending neuritis," using this term as meaning the ascent of the poison, later he and Laroche demonstrated the affinity of the toxin to the phosphorized lipoids of the brain, which are present in greatest quantity in the grey matter. Confirmation of the neural transmission of toxins was forthcoming when Orr and Rows demonstrated that toxins and organisms could ascend to the central nervous system by way of the perineural lymphatics. Walshe in his interesting papers upon the pathogenesis of diphtheria accepts this lymphogenous infection as the probable explanation of the local paralysis. As clinical evidence he cites cases reported in literature, and brings forward new evidence as the result of his observations upon numerous cases of wound diphtheria, in some of which he was able to establish definitely the local association between the point of infection and the initial paralysis.

The specific paralysis—the paralysis of accommodation—which occurs irrespective of the site of the local lesion, and generally before the third week, appears to be due to the selective action of the toxin on the ciliary muscle. The reaction of the pupils to light is never affected, and the interference with the power of accommodation is manifested by the difficulty the patient experiences in reading small print rather than by any demonstrable paralysis of accommodation.

Multiple neuritis is a later development, and may follow any local infection. Its onset is insidious, and its presence may not be suspected until the patient attempts to walk during convalescence, long after he has recovered from his palatal paralysis, although examination might have recorded a loss of the deep reflexes. It is characteristic of the disease, therefore, for the paralysis to be developing in one part while it is retrogressing in another. The

changes are more pronounced in the nerves, especially at the periphery, than in the ganglion cells, and this is borne out clinically by the fact that complete recovery may take place even in severe cases. It has always been difficult to explain the generalized paralysis on the basis of a local ascending infection. It seems to me possible that the toxin in the blood invades the nervous system by way of the neural lymphatics generally, and that its incidence upon the nervous system is due to its selective action. The whole question, however, requires further investigation.

Acute, Subacute, or Chronic Infections with their Incidence chiefly on the Nervous System

I have selected this title for the group in which I have placed those cases which have been described under various names—such as acute toxic polyneuritis, acute febrile polyneuritis, acute infective polyneuritis—and I propose to add to them cases described as Landry's paralysis, which I submit are essentially similar.

In Landry's paralysis the onset may be abrupt, with the characteristic ascending paralysis commencing at the periphery of the lower extremities, and ascending to involve the trunk and upper limbs, and even the facial muscles, provided death has not resulted from respiratory paralysis. The paralysis is of the flaccid type, is painless, the superficial and deep reflexes are abolished in the affected areas, and transient difficulty with micturition occurs when the paralysis invades the trunk muscles. Sensory disturbances are minimal, rarely exceeding a mild paraesthesia in the extremities. These may be followed by slight impairment of cutaneous sensibility, and pruritus and cramps in the muscles, with a moderate degree of tenderness.

In many instances the onset is not so abrupt, and may be preceded or accompanied by feelings of malaise, headache, pruritus in the back and limbs, gastric disturbances, and slight fever. The paralysis may be of a descending type, and may even in some cases appear to spread from the site of onset both upwards and downwards. As a rule its spread is continuous and steady, but sometimes a halt is observed, to be followed later by further extension. The weakness is more apparent in the proximal muscles than in the distal, but I think that this is due to a gravity effect, for if the limb is supported it is often possible to demonstrate movement in muscles which were apparently completely paralyzed. Muscular atrophy is never severe, and recovery takes place first in the last affected muscles.

If we compare this with the descriptions of acute febrile or acute infective polyneuritis given by Holmes, and by Birdford, Bishford, and Wilson, we find no material difference. Holmes describes a rapid onset with malaise and slight fever, followed two or three days later by pruritus in the legs and lower part of the back, and paresis of the lower extremities with toneless muscles. Extending from the toes upward the paralysis affects the trunk muscles, arms and face, the facial palsy being a characteristic feature, although sometimes of slight degree. Occasionally ocular palsies were observed, but the other cranial nerves were not affected. The deep reflexes were abolished, and there was transient difficulty in passing water. The sensory disturbances were never marked, pain was not severe, and there was only slight tenderness on pressure. Some loss of sense of position and of vibration was present in the feet, and some cutaneous stimuli were painful. The paralysis reached its maximum in from seven to ten days, and recovery was well advanced by the fourth week.

Birdford, Bishford, and Wilson's series of cases were essentially similar, but in some instances there was evidence of an initial illness preceding the onset of the paralysis, the latent period between the fever and paralysis varying from five days to six weeks. The paralytic stage in its mildest form was little more than a more or less rapid onset of general weakness with involvement of the face. In severe cases the onset was sudden, affecting first the legs, and rapidly ascending to the trunk, arms, and face within two or three days. They noted weakness, especially in the proximal muscles, but no paralysis of special muscles

or groups of muscles. The bilateral facial palsy was the most distinctive feature. The palsy was of the flaccid type with abolition of the deep reflexes. Micturition was only interfered with slightly. There was never any paralysis of the pupillary reactions. The sensory symptoms were pruritus in the head, back, and limbs, at the onset, pruritus and paraesthesia in the extremities. Anaesthesia and analgesia were detected in the distal segments of the limbs, occasionally in the face, and rarely in the distribution of various spinal roots. The mortality was high, eight deaths occurring in thirty cases, generally before the seventh day, and often suddenly without previous warning. In the non-fatal cases recovery took place slowly.

As a result of their investigations they concluded (1) That so-called acute febrile polyneuritis is a very definite clinical entity, capable of being separated clinically from other diseases of the nervous system. (2) That it is a diffuse affection of the nervous system, affecting the spinal cord, spinal ganglia, and the peripheral nerves. (3) That the lesion essentially affects the nerve elements and fibres, with but a slight incidence on the cortex. (4) That it can be transmitted experimentally from man to monkey and the characteristic lesions reproduced.

I have personally observed several cases of Landry's paralysis, and over twenty cases of acute toxic polyneuritis. In some of the latter the diagnosis was based solely upon the development of sensory disturbances ten or fourteen days after the onset of the paralysis, and had death occurred before they would certainly have been accepted as being typical of Landry's original description.

Now in all these cases we have the following resemblances:

(1) An acute ascending paralysis of the flaccid type, with abolition of the deep reflexes. (2) A febrile onset. (3) Only slight disturbances of sensibility. (4) A moderate degree of pruritus and tenderness of the muscles at the onset. (5) Slight and transient interference with the sphincters. (6) An absence of mental changes. (7) No constant change in the cerebrospinal fluid, which is often normal, or may contain an excess of protein.

Cases of recurrent multiple neuritis have been described. It is to be noted in these cases that the symptoms are predominantly motor, that each attack leaves the patient weaker than before, that there is always more wasting than is usually found in multiple neuritis, that the attacks occur without any known cause and at irregular intervals, and finally, that in the intervals certain of the tendon reflexes cannot be elicited, and indeed seem to be permanently abolished.

Acute interstitial poliomyelitis has, as a rule, a perfectly distinct and definite clinical picture, but in its typical forms it may resemble acute febrile polyneuritis—as, for example, in acute ascending poliomyelitis, and again, some cases have been reported in which it has been associated with multiple neuritis. The cases which Brines described under the name of "toxic degeneration of the lower neurones" were not unlike cases of recurrent polyneuritis, and the question as to the incidence of the affection upon cell or fibre only emphasizes the neuronic aspect of all forms of toxic multiple neuritis.

In view of all these facts we must agree that it is no longer possible to limit our conception of multiple neuritis to one in which the peripheral nerves alone are affected. We must force ourselves to think in terms of neurones, not of nerves, and to study cases clinically from the point of view of functional disturbance or, more correctly, interference with function. It is illogical to separate a nerve cell from its fibres, they are essentially one from the point of view of function, and interference with either must, and does, affect both.

In all cases of toxic affection of the nervous system the element of selectivity is present in greater or less degree, and the greater the degree the more specialized will be the functional disturbance. Further, the selective action is not necessarily directly due to a primary action on the nerve elements proper, it may be to its affinity for the chemical elements of the tissues in which they lie. The other factor, the path of infection and its influence in determining the clinical function, has already been referred to.

SYMPTOMATOLOGY

In our review of some of the various forms of multiple neuritis we have noted the special features—motor, sensory, or trophic—typical of each. It only remains for me to sum up those features which are common to all and upon which the diagnosis of multiple neuritis must be founded.

General Features

- 1 The spontaneous onset of the symptoms, which may develop rapidly or slowly
- 2 The evolution of the clinical picture, which is characteristic and occurs in three stages
 - (a) A stage of invasion
 - (b) A stage of elaboration, in which the symptoms and signs are fully developed, this may end in the death of the patient or, more frequently, in
 - (c) A stage of recuperation, which may be prolonged
- 3 The symmetry and bilaterality of the symptoms in each individual case as regards—
 - (a) Their distribution
 - (b) The character of the functional disturbance
 - (c) The time and order of their recovery

GENERAL DISCUSSION

Dr WILFRED HARRIS (London) suggested that Dr Cragie Stewart's classification might be further simplified by leaving out Groups C and D. Group C for neuritis of obscure origin, including rheumatic, would appear to be sufficiently provided for under the metabolic and infective groups of endogenous toxins, while Group D—local infections of nerves (leprosy and chronic interstitial hypertrophic neuritis)—should not be considered as instances of multiple neuritis, which essentially meant a toxic neuritis, not a local damage to nerves, even though many be affected. The psychosis described by Korsakoff nearly forty years ago was certainly not limited to polyneuritis of alcoholic origin. It was doubtless an example of the toxemia affecting cortical cell groups, in encephalitis, and was evidence that the circulating toxin might damage two distinct parts of the nervous system at the same time. Some cases of polyneuritic psychosis left a sequel permanent mental enfeeblement, so that the man might be capable of only the very simplest work, his memory for orders and his capacity for detail or for initiative being almost nil. A parallel condition was seen in saturnine encephalopathy, in which convulsions, delirium, and coma occurred, indicating a form of encephalitis while at the same time spinal nerve cells and peripheral nerves might suffer from the lead poisoning. Dr Stewart was attracted to the generalization of the lower neurone as a whole, nerve cell as well as peripheral fibre being the victim of the toxemia of polyneuritis, and he had instance lead neuritis as an example of segmental neurone disease of nerve cells as well as of nerve fibres. With this thesis Dr Harris could not agree. In severe wrist-drop of lead palsy the radial extensors of the wrist were completely paralysed, though the supinator longus escaped, yet both were equally supplied by the fifth cervical segment. Indeed, the motor palsy of lead wrist-drop, with no sensory involvement, was clearly a posterior interosseous neuritis. Again, in the upper arm type, in Dr Harris's experience, it was especially the deltoid that suffered, the biceps very little, and the supinator longus not at all. Textbooks seemed to copy one another in describing the upper arm type of lead palsy as resembling Erb's palsy, though there was a type of progressive atrophy due to lead in which this segmental distribution of the muscular paralysis was found. When the toxemia struck the nerve cells in the anterior horns, then the resulting paralysis was segmental in distribution, and might be stationary or progressive, but did not recover, though lead neuritis, which was neuritic in distribution and non segmental, did recover. A good instance of this was the subacute paralysis and atrophy of the intrinsic muscles of the hands which sometimes accompanied the wrist-drop of lead palsy. The wrist-drop ultimately recovered, but the atrophy of the hand muscles, being due to a subacute polymyositis of the distal segment, was permanent. Serum disease had often

been alleged as a cause of multiple neuritis, but these cases required careful scrutiny, and in cases of septicemia, typhoid, diphtheria, etc., in which polyneuritis had followed the administration of serum, it was more than probable that the neuritis should be ascribed to the toxins of the primary disease, and not to the serum used in the treatment. During the war, when such vast numbers of men were treated with antitetanic serum, Dr Harris was one of the two tetanus inspectors for the London area, and he came a great deal into contact with tetanus cases and the routine use of antitetanic serum, both for wounds and in the treatment of tetanus, yet he saw no case of polyneuritis follow in any case of myophaxia or other phenomena due to serum treatment. Dr Stewart's reflections on Landry's paralysis interested Dr Harris much, and he congratulated him on including such cases as instances of multiple neuritis. The speaker had never seen a case of so-called Landry's paralysis which could not better be described either as polyneuritis, polymyositis or as an ascending myelitis. As a separate clinical syndrome he did not believe that Landry's paralysis existed.

Dr W. JOHNSON (Liverpool) proposed to limit his part in the discussion to the consideration of a few special points. As regards the causation of multiple neuritis, they were all agreed on the main principle that toxins—whether chemical, metabolic, or bacterial in origin—were the essential factor in the production of the disease. Comparison of statistics by different individuals was certain to show slight variation as regards the relative frequency of any particular toxin as the causative factor. In his own practice he found lead palsy formed a prominent group, and that, indeed, lead formed a serious rival to alcohol, which was commonly accepted as the most frequent cause of multiple neuritis. Following them, but represented by only a few cases, came diabetes, influenza, diphtheria. Other causes, in his experience were extremely rare. Usually in every case of multiple neuritis systematic examination of the patient led to a hint which enabled them to identify the toxin which was responsible. At the same time, one continually came across cases which were definitely atypical. It was the atypical cases to which Dr Johnson wished to draw attention. They were accustomed to teach that it was the "selective action" of the various toxins that produced the differing forms of peripheral neuritis, and then conception of modern neurology demanded that they accepted this principle of "selective action." Actually, however, certain of the atypical cases seemed to flout this theory and they were compelled to look round for some additional explanation. Dr Johnson had always been interested in such cases and it seemed to him that they were obliged to consider the influence of an additional factor—namely, fatigue. The late Professor Edinger of Frankfurt attached great importance to the effect of fatigue on nervous structures in predisposing them to the action of toxins, and his view might be summarized as follows: "In any condition, where toxins were circulating generally through the system, the poisoning effects were liable to occur chiefly in those structures which had been the seat of fatigue." Many other workers too had laid stress on the deleterious effect of fatigue on nervous structures. He thought lead palsy formed a good example of Edinger's theory. The textbooks stated "Lead chiefly affects the musculo-spiral nerve, but differs from musculo-spiral paralysis in sparing the supinator longus and sometimes the extensor ossis metacarpi pollicis." Then a little further on—"There is another type of lead palsy, however, in which the shoulder and upper arm muscles are mainly affected, the wrist extensors being only slightly paralysed." In the light of the fatigue theory, inquiry into the exact occupation of the atypical cases formed by this second group had frequently proved of real interest. For the occupation leading to the common type of lead paralysis—namely, wrist-drop palsy—was that of the ordinary printer, who used a free flexion and extension movement of his wrist. This type was commoner in the right hand, but if the patient was left-handed, as occurred in one of Dr Johnson's patients, then the paralysis was most marked in the left hand. When they considered that it had been estimated that a printer performed no fewer than 3,000 extensions of his wrist each hour in the performance of his work, it would surprise no one that in the presence of a toxin the neuromuscular

mechanism of the wrist extensors should give out. Such a statement clearly meant that the question of fatigue was not one which could be ignored. The upper arm type of lead palsy, on the other hand, occurred in an entirely different form of occupation—one which, he was told, was known as "puddling"—in which the work consisted in using a heavy scraper requiring considerable strain on the shoulder muscles. Again—as a blow to the "selective action" theory—in the textbook they read "But in some cases the supinator longus is also involved in the paralysis." In one such case which Dr. Johnson saw it appeared that the man was a printer using a heavy form of brush necessitating a movement in which the supinator longus was used. In this case too there was complete weakness of the flexor pollicis, which muscle was also much involved in the movement. Finally, it might be noted that those muscles which were specially liable to fatigue—that is, the extensors of the wrists and ankles—which were anatomically set at a mechanical disadvantage as compared with the flexor muscles—were the ones which exhibited the most severe degree of paralysis in multiple peripheral neuritis. These points might not be altogether beyond controversy, and it would be interesting to learn whether other members present had anything in their own experience which could be advanced in favour or otherwise of the relative importance of this "exhaustion" theory. The President, by his writings in the realm of psychology, had made the theme of the importance of fatigue and exhaustion very much his own. It seemed to Dr. Johnson that observations in neurology were tending to make them follow along the lines of his teaching—which to his own knowledge went back over twenty years. It was now recognized that fatigue undoubtedly had a deleterious effect on the neurone, and he believed it played an important part in undermining the resistance of nervous structures to any toxin which might be present and in this way determined the distribution of symptoms in individual cases.

Turning to the symptomatology of multiple neuritis, Dr. Johnson proposed to give in short detail a brief account of the somewhat rare condition, namely infective polyneuritis, two cases of which had come under his notice recently.

The first was that of a man aged 35. One week before his symptoms appeared he had a slight chill sustained after sitting on some damp grass. The chill however, was very transient and unfortunately his temperature was not taken. When he consulted his doctor he complained that for two days his legs had been lightly weak and painful and his walking unsteady. He was kept in bed and on the fourth day after the onset of the weakness the pains had extended to the sacral and lumbar regions and were so severe as to keep him awake all night. On the sixth day the pains were still present and facial weakness had appeared. On the seventh day—which was when Dr. Johnson saw him—the legs showed flaccid paresis, the knee jerks and ankle jerks were absent, the arm jerks were diminished and were barely elicited. Both sides of the face were almost completely paralysed, the paralysis being of the infranuclear type. There was some subjective numbing of the extremities experienced by the patient but no absolute loss of any form of sensation could be demonstrated. Ordinary stimuli applied to the hands and feet showed the presence of slight hyperaesthesia.

A gradual improvement was noticed up to the end of the second week—the only untoward symptom being the rise of the pulse rate to 120. The facial weakness notably improved, and the patient was enabled to swallow better and to speak more distinctly. The deep reflexes however did not return. On the sixteenth day following the onset of his neuritic symptoms he was seized with severe respiratory embarrassment, the diaphragm became paralysed in the course of twenty-four hours and death resulted.

The second case that of a lady aged 33 recovered after passing through a very critical illness. The history was that three weeks after a very difficult labour in which the child was stillborn she commenced to run an irregular temperature, which mounted to 103° for the space of about a week. At the end of this time she began to notice paraesthesia of the hands and she described the sensation as everything she touched seemed to be hot, even a glass of cold water felt hot. There was shooting pain in both upper arms and the legs felt slightly weak. In the third week of the illness—during which Dr. Johnson saw her—the arms and legs were pronouncedly weak and flaccid. The tendon reflexes were much diminished and facial palsy had suddenly appeared on the left side and within a day or two had spread to the right side. Sensation was markedly defective to cotton wool, pin prick and vibration over fingers and toes and the skin was smooth and glossy. The diminution of sensation was variable, and affected some digits more than others. During the fourth week the pains continued and were very severe in the legs. Both arms and legs now showed slight general wasting. From this time on slow improvement occurred, the left side of the face being practically recovered by the sixth week, but the right side

remaining partially paralysed. Power in the legs was much improved by the tenth week and during the twelfth week the patient was able to stand a little.

The ultimate history in this case was that the patient made a slow recovery and now was able to go about ordinarily but tired very easily. The right side of the face still remained partially weak and—an interesting point—she still suffered from recurring periods of tingling and a cold sensation in the feet and hands. Considering the severe degree of paralysis which had occurred one must regard her recovery to her present stage as very satisfactory.

As regards the electrical reactions in this case it might be added that the weak muscles never at any time ceased to react to faradism, although in certain instances the response was very meagre.

One other case of this interesting disease had come under Dr. Johnson's observation. It was that of an officer in France during the war. The history obtained was that he had suddenly collapsed whilst on parade, and when seen by Dr. Johnson three or four days later he had flaccid paralysis of all four limbs, together with slight facial weakness. He was evacuated to the base, and unfortunately no information as to the further developments in his case were available. Prior to the description by Gordon Holmes, Rose Bradford, and his colleagues these cases were included under the term "Laudry's paralysis", Dr. Goring Stewart had already dealt with that question. The etiology of all three cases described was of interest, because there was a definite connexion with war service abroad, two had been officers serving in France, and in the third case—that of the lady—the symptoms followed the transfusion of blood from her husband, who had also served abroad.

Dr. F. J. NATTRASS (Newcastle-on-Tyne) drew attention to the occasional occurrence in cases of multiple neuritis of enlargement and hardening of the peripheral nerves, a condition he had met with in two cases. One of the cases was also remarkable by reason of its recurrent or relapsing character.

The first case was a male aged 22, whom Dr. Nattrass first saw four years ago. A fortnight before admission to hospital he began to have pains and numbness in all his limbs, rapidly followed by loss of power first in the legs and then in the arms. He became almost completely helpless in three days. On admission he presented the evidences of a widespread peripheral neuritis. There was marked weakness of the facial muscles and some difficulty in articulation. Nearly all the muscles of the upper and lower limbs showed atrophic paralysis. Weak voluntary power was present in the upper limbs but there was complete flaccid paralysis below the knees. In addition there was much weakness of the trunk muscles. All the tendon reflexes were absent. There was a degree of reaction of degeneration in the muscles of the limbs which became complete in the hands and in all the muscles below the knees with characteristic slow response to galvanism; the peronei and calf muscles gave no response to either current. There was no objective loss of cutaneous sensibility, but some loss of vibration sensation in the legs. The weak voluntary movements of the upper limbs were accompanied by a coarse tremor and the sense of position was very defective. Astereognosis was well marked in the hands, together with defective tactile discrimination. There was great tenderness of the muscles. On palpation such peripheral nerve trunks as could be felt—namely, the median ulnar and external popliteal—were extremely tender and were very definitely enlarged and felt hardened. The enlargement was uniform and the nerves appeared to be about one and a half times to twice their normal diameter. There was no fever, the Wassermann reaction was negative and the blood and cerebrospinal fluid showed nothing abnormal. Slow recovery occurred in three months functional recovery was complete within six months, the tendon reflexes had returned and the electrical reactions were normal. Also the nerve trunks returned to their normal size.

A year previously this man had been in hospital with a precisely similar attack from which he had recovered completely. At the age of 4 he had apparently exactly the same illness and recovered in six months. He had had a slight relapse a year ago which was apparently arrested by massage and electrical treatment and this year was again in hospital with a severe attack. The clinical features of the latest attack were exactly as before and he is now again almost recovered. The hypertrophy of the nerve trunks was again obvious and on this occasion there was a similar enlargement and hardening of a few superficial nerves in the neck and legs. Portions of the left great auricular nerve and of the musculocutaneous nerve of the right leg were removed for histological examination which was carried out by Dr. A. T. Bernard Shaw. The histological examination was very complete but largely negative. Sections stained by Gram showed no microorganisms and no evidence of nerve degeneration was observed by Weigert's method. Some hundreds of serial sections stained by haematoxylin and eosin or haematoxylin and van Gieson were made without revealing any anatomical changes except some oedema of the nerve sheath. However, in a longitudinal section of a portion of the great auricular nerve a precapillary venule situated in the adventitial tissue at some distance from the nerve showed perivascular infiltration with inflammatory cells of large mononuclear type.

The second case a man of 42, was recorded by Dr I. G. Hobson of Oxford. The case was shown to the Association of Physicians at Oxford in 1922, when Dr Nattrass had the opportunity of seeing it. Following an attack of influenza this patient developed widespread peripheral neuritis affecting the cranial nerves and all the limbs; sensory disturbance was marked as well as atrophic paralysis. Associated with this was obvious hypertrophy of nerve trunks chiefly in the upper limbs and also of superficial nerves. The cutaneous nerves of the cervical plexus stood out prominently and formed a striking picture. This man made a slow but complete recovery. He had a slight relapse of the symptoms and returned for treatment, but he had again recovered and was back at heavy work.

Dr Nattrass could offer no explanation of the recurrent attacks seen in the first case. He could find no evidence of focal sepsis and no indication of intestinal toxæmia. Dr Wilfred Harris had considered the question of recurrent polyneuritis in his presidential address to the Section of Neurology of the Royal Society of Medicine, pointing out that lead and alcohol were occasional causes, and that after lead poisoning recurrences of palsy might take place without any fresh exposure to the poison. Dr Harris referred to seven or eight cases of recurrent polyneuritis of doubtful etiology which had appeared in the literature during the past thirty years; the description of some of these read very similarly to this case, especially one that had been described by Dr F. G. Thomson, the President of the Association. The explanation generally put forward was that the first attack left the nerves with a lowered power of resistance, or hypersensitive, to an unknown toxic factor. The absence of any definite inflammatory reaction in the nerves examined histologically suggested the possibility of an exudative condition of interstitial type rather than an inflammatory process, and that was supported by the complete resolution between the attacks. Apart from leprosy, hypertrophy of the peripheral nerves appeared to be a rare condition. So far as Dr Nattrass knew it had not been recorded in any of the well recognized forms of multiple neuritis such as plumbism and alcoholism. In 1893 Dejerine and Sottas described two cases under the name of "progressive interstitial hypertrophic neuritis of infants," a family disease in which hypertrophy of the nerves, superficial and deep, of a uniform character was well marked, one case was examined pathologically, and in interstitial fibrosis of the nerve trunks and posterior nerve roots was found, together with consecutive sclerosis of the posterior columns of the cord. Those cases were, however, very chronic and showed no tendency to remission. Similar cases, in adults as well as children, had been published by Pierre Marie, Dide and Courjon, and Schaller. That of Schaller approached more nearly the two cases Dr Nattrass had described as it commenced at the age of 13 years, there was no family history, and considerable improvement followed the administration of arsenic by the month and galvanism to the muscles. In that case the superficial cervical nerves and the cutaneous nerves of the forearms were enlarged, and sections of a portion of one of them removed during life showed the appearances of interstitial neuritis described by Dejerine.

Dr S. A. Kinnaird Wilson (London) considered that the term "multiple neuritis" in many of the cases under discussion was a misnomer. In addition to the peripheral nerves, there were often changes in the cells of the anterior horns and even in the muscles—for example, in lead neuritis. When no sensory symptoms were present a better term was "neumonitis," or if multiple lesions "polymyoneuritis." He was not impressed by Edinger's theory of fatigue, in the example of the printer mentioned by Dr Johnson the flexor muscles contracted just as much as the extensors. No mention had been made of the condition known as "central neuritis," in which the medullated fibres of the central nervous system were involved, normally as part of a toxic process.

Dr Worster-Drought (London) referred to the occurrence of nystagmus as an occasional phenomenon in multiple neuritis, more particularly in the alcoholic form. At the present time he had under his care a case of alcoholic neuritis, that of a woman aged 36, addicted to spirit drinking who also exhibited Korsakoff's psychosis and pronounced nystagmus. He had also met with

nystagmus in cases of lead, diabetic, and post diphtheritic neuritis. With regard to a question raised by Dr Granger Stewart, he (Dr Worster-Drought) had seen the actual symptoms of diabetic neuritis improve both on diabetic treatment alone and on insulin injections, but there was no return of the deep reflexes. An interesting although somewhat infrequent form of polyneuritis—or more strictly polymyoneuritis, as the anterior horn cells were probably affected and sensory changes often absent—was syphilitic neuritis. This condition, when it developed, usually appeared rather late in the secondary stage and was characterized chiefly by muscular weakness and atrophy, changes in electrical excitability, and loss of deep reflexes. On appropriate antisyphilitic treatment (not a combination intravenously, etc.) the prognosis was exceedingly good and most cases recovered completely, although the ankle jerks might be permanently abolished. Of two cases which Dr Worster-Drought had had under his care during the past few years, both occurred in young men five and eight months after infection respectively. In the first case the upper limbs were the more affected, and there was some loss of cutaneous sensitivity; under treatment however, complete recovery ensued within three months. The second case was more profound, the lower limbs being chiefly involved, but no sensory changes were present. Apart from absent ankle jerks, this case also recovered within three months. One must be taken not to confuse syphilitic polyneuritis with the neuritis that might result from treatment with arsenic and/or compounds, in the latter the ankle jerks were usually lost, and occasionally the knee jerks, but there was very rarely any muscular weakness or atrophy. The polyneuritis could scarcely be mistaken for early tabes dorsalis as in the former pupillary changes were absent, and the period from the original infection to the date of onset was too short for tabes. In Dr Wilfred Harris, he (Dr Worster-Drought) had also acted as a tetanus inspector during the war, and he entirely agreed with Dr Harris as to the extreme rarity of neuritis resulting from serum injections. In many serum-treated cases of tetanus and cerebrospinal fever, and innumerable patients who had received a prophylactic dose of antitetanic serum as well as a dose of mephitoxin he had never met with an example of multiple neuritis that could be attributed to serum. Recurrent multiple neuritis was an interesting form of polyneuritis, but the etiology was most obscure. For the past fourteen months Dr Worster-Drought had had under observation a case of this type.

A man aged 40 in whom the original attack started with acute gastric symptoms—vomiting for three days followed by light jaundice—and the subsequent recurrence eight months later had appeared in an exactly similar manner. Following the original attack of vomiting paresthesia developed in the hands and feet the deep reflexes were rapidly lost the limb muscles became flabby, parietic, and later somewhat atrophied with diminished or absent reactions to faradism; loss of cutaneous sensibility and defective deep pressure and postural sense also developed in the distal portions of the limbs. Neither the face nor other cranial nerve were involved the liver was not enlarged or tender and the other systems showed no abnormality. No hypertrophy of the peripheral nerves such as Dr Nattrass had described was present. After three months the patient had made a good recovery, was walking and using his hands normally and felt quite well. Five months later the recurrence took place, the onset being accompanied by intense nausea and vomiting for two days. Again paresthesia and all the previous signs of multiple neuritis rapidly developed. On this occasion there were certain definite though slight mental changes—depression slight confusion and a loss of memory for recent events. With this second attack even after five months, recovery was not quite complete, a certain amount of muscular weakness in both arms and legs persisting.

The case was investigated as fully as possible. The man had never been abroad, arsenic administration could be definitely excluded, and at no time had there been contact with lead. No focal sepsis could be demonstrated the tonsils were and accessory sinuses of the nose all being normal and x-ray examination of the feet showing healthy alveoli and periodontal membranes. The urine showed no abnormality chemically or bacteriologically. Bacteriological examination of the faeces revealed nothing of note—streptococci were fewer than normal cultures on McConkey lactose agar plates grew only lactose fermenters. A negative Wassermann reaction was obtained in the blood and cerebrospinal fluid and the latter was normal in all respects. The blood count only was of interest owing to the marked reduction in the number of polymorphonuclears and the relative increase of the small lymphocytes—namely, red blood cells 4,620,000 and white blood cells 6,200 per cubic millimetre polymorphs 35 per cent lymphocytes 63 per cent (small 61.5 and large 1.5) eosinophils 0.5 per cent mast cells

15 per cent Colour index 0.82, and haemoglobin 75 per cent. The causal factor in this case appeared to be some unknown toxic agent.

Dr A F HURST (London) drew attention to the important subject of latent neuritis. It was not uncommon to find in alcoholic individuals definite signs of peripheral neuritis which had given rise to no symptoms of any kind. In a suspected case of alcoholism the diagnosis received very strong confirmation if the ankle-jerks were found to have disappeared. Less frequently the knee-jerks were also lost, but they were often normal or only slightly reduced and were sometimes even exaggerated when the ankle-jerks were unobtainable. It was very rare for the reverse to occur and the knee-jerks to be absent when the ankle-jerks were still present. Associated with the loss of tendon reflexes there was more or less tenderness of the calves, in contrast with the analgesic calves with which the lost jerks of tabes dorsalis were associated. Several years ago,¹ with Dr W. Johnson and Dr Gordon Goodhart, Dr Hurst had pointed out how rarely alcoholic neuritis, whether latent or obvious, occurred in association with alcoholic gastritis and cirrhosis of the liver. On the other hand, his experience was in complete accordance with that of R. T. Williamson,² who observed that latent neuritis was invariably present in cases of alcoholic heart. The pathological basis of the heart failure occurring in chronic alcoholism had long been a mystery, as there was no anatomical evidence to support the theory of myocarditis or even of myocardial degeneration. As these cases were always associated with latent neuritis, and as, so far as Dr Hurst's experience went, obvious alcoholic neuritis was always associated with some degree of persistent tachycardia, it seemed not unlikely that the cardiac condition depended upon a vagal neuritis. A further point of interest was that alcoholic heart was very rarely associated with cirrhosis of the liver, in the only two cases he had seen in which an alcoholic heart appeared to be associated with cirrhosis of the liver, the large, hard liver was found, *post mortem*, to be nutmeg and secondary to heart failure and not cirrhotic. It appeared, therefore, that the poisons which produced alcoholic cirrhosis were not the same as those which produced alcoholic neuritis and the frequently associated cardiac condition. The former were almost certainly toxins, which resulted from the disturbed digestion caused by the gastritis with which it was always associated, the gastritis was a direct result of alcoholic irritation, and the toxins which were produced in the alimentary tract gained access to the liver by the portal vein. As Dr Grainger Stewart had pointed out, the neuritis was probably directly due to the action of the alcohol circulating in the blood on the nervous tissues. Chronic cerebral alcoholic poisoning was probably caused in the same way, as those cases in which obvious symptoms of neuritis were not present were almost always associated with evidence of latent neuritis. In contrast with this Dr Hurst had been surprised to note how often the ankle- or knee-jerks were still present in patients with delirium tremens or in dipsomaniacs. Latent neuritis was also very common in diabetes, as Williamson³ was the first to show. Wherever cramp or more serious symptoms of neuritis were not very common, loss of deep reflexes and some tenderness of the calves were present in over 40 per cent of cases.

As in alcoholic neuritis the ankle jerks were almost always lost earlier than the knee-jerks, it was regrettable that the importance of the ankle jerks was still not recognized as widely as it should be, if the state of the ankle-jerks as well as that of the knee-jerks were asked for by insurance companies, many cases of early tabes and of chronic alcoholism would be recognized, which at present passed as first class lives. Lastly whenever arsenic was given medicinally in large doses the ankle-jerks should be tested at least once a week, as their disappearance always preceded the occurrence of obvious symptoms of neuritis. If this precaution were always taken, the severe cases of arsenical neuritis which occasionally developed in patients under treatment in bed for skin disease, chorea, or Addison's anaemia would never occur.

In the unavoidable absence of Dr JAMES COLLIER (London) his contribution to the discussion was read by Dr E. M. POTHER. Dr Collier considered that it was peculiarly fitting that Dr Grainger Stewart should have opened that discussion upon multiple neuritis for he was carrying on the tradition of his father, Sir Thomas Grainger Stewart, who wrote the very first monograph upon the subject in the English language, forty-five years ago, and thereby set up a milestone in English neurology. There was little or nothing in Dr Stewart's opening address with which Dr Collier was at variance or which he could not cordially endorse. In the picture which had been given of polyneuritis as a neuromic affection, and not as a systemic affection, and, further, not of the lower level of motor and sensory neurones only, but indeed always potentially pan-neuromic, he would like to bring into the discussion the frequency with which one saw myasthenia in conditions of polyneuritis—already mentioned by Dr Woistell-Drought—and suggest that there was an affection of the cerebellar neurones. He also had at the present time under his care a case of severe alcoholic neuritis with Korsakoff's syndrome in which there was myasthenia so marked and of such a type as to leave him with the absolute conviction that it was only explicable on the ground of an affection of the cerebellar neurones. Again, as regards the affection of the cerebellar neurones in polyneuritis which was productive of Korsakoff's syndrome and the various mental disturbances and reductions seen in alcoholic neuritis and of the "encephalopathies" met with in polyneuritis from lead, copper, and other metallic poisons, Dr Collier wished to submit his opinion that like symptoms pointing to derangement of the functions of the highest part of the nervous system were to be expected and should be sought for in every form of polyneuritis, from any cause whatsoever, and if sought for they would be found much more often than was at present generally recognized. He had encountered such symptoms in almost every variety of polyneuritis that he was acquainted with, and he thought that they should be placed upon the roll in the descriptions, as possible symptoms of every form of polyneuritis. Concerning the symmetry of distribution of the signs of polyneuritis upon the two sides of the body which was so deeply impressed upon students of Dr Collier's day by the term "multiple symmetrical peripheral neuritis" which headed the monographs written at that time upon the subject, for the purpose of freeing their minds from any necessity of symmetrical distribution in this malady, he wished to say that he once admitted under the care of the late Sir William Gowers a case of typical lead polyneuritis confined to one side, and this patient made complete recovery without the slightest sign of affection of the other side, leading that distinguished neurologist to withdraw the law he had laid down—that if a wrist-drop did not become symmetrical within six weeks it could not be caused by lead poisoning. Dr Collier had seen alcoholic neuritis strictly confined to one side of the body for the first few days of the symptoms. Now these were cases in which a blood distributed poison had produced an asymmetrical affection. When they considered those forms of polyneuritis in which a local dose of a poison was delivered along the nerves into one definite spot of the nervous system, perhaps on one side only, they would not expect the resulting paralysis to be symmetrical, if the poison spread but slowly within the nervous system and the advent came to an end soon. That was what was always seen in the external ophthalmoplegia of diphtheria, which Dr Collier submitted, was never symmetrical, and again in the common paralysis of a wounded limb alone when diphtheria had infected a wound. He had during the past few years come across five cases of polyneuritis in which the asymmetrical distribution was very striking. They were examples of the spreading variety of polyneuritis akin to the Landry type in which paralysis commencing in the shoulder spread to the fire and hand of one side. In all of them there was rapid and complete recovery and a suggestion that the origin of the toxin was in the throat. They were not in reality unilateral cases for the reflexes were lost in the opposite arm, but the complete paralysis upon one side and the unimpaired movement upon the

other presented a picture which a great many people would refuse to accept as that of a polyneuritis. The nature of the affection of the neurone in polyneuritis must surely be that of fixation of the poison in the protoplasm, whereby the metabolism was so changed as in some instances to abrogate function very rapidly, in others more slowly, in a few to kill the neurone outright. In some examples there could be no structural change in the affected neurones, for the paralysis, so rapid in onset and so complete, might pass off in so short a time as to preclude any question of degeneration and regeneration. For example, the facial polyneuritis in tetanus from a wound of the face did one ever see more complete bilateral facial palsy than in that condition? Yet it might be all recovered from in three weeks. Again, in diphtherial palsy it was common to see rapid recovery of the palatal palsy. Landry's paralysis, which he was glad to see placed in its proper position as a polyneuritis by Dr Stewart, might also recover very rapidly and completely. He had seen arsenical neuritis from a single dose of poison, and also alcoholic neuritis from medicinal administration in an unsuit subject, recover with altogether unusual and startling rapidity.

Dr Collier was convinced that when there was a strictly nematic distribution of the affection in polyneuritis, as when the face alone or the face and arms alone, or the trunk alone, were affected, the rest of the body completely escaping, and also in the "ascending," "descending," and "spreading in both directions" types of polyneuritis, that these were always matters of a local dose of poison delivered into the nervous system at that metameric level which was first and most affected, and he theorized that it was from the alimentary canal that these local poisons started. He would warn against the set types of symptoms and signs which they all had to cling to in writing textbooks and in teaching students, and would ask acceptance of a lead paralysis with deep sensory loss, a diphtherial paralysis with absolute "glove and stocking" loss to all forms of sensibility, a lead paralysis with no diplopia but with complete flexor paralysis in alcoholic paralysis with a similar flexor paralysis, an alcoholic paralysis with deep sensory loss and great pain and tenderness, yet with no paralysis whatever and with all the deep reflexes intact, as examples of the varieties of polyneuritis, which in the past had been driven along the confines of too narrow a description. Lastly, Dr Collier drew attention to a new variety of polyneuritis which he hoped would not remain long with them that variety due to the too enthusiastic and unduly prolonged administration of bacterial toxins in the form of vaccines. Those who were acquainted with the works of Rothman, of Orr and Ross, and of E. Long and Midline Long upon the effect of prolonged administration of bacterial toxins in animals, in causing appalling and unhealable degenerations within the nervous system would, he was sure, be very careful with regard to the prolonged administration of bacterial vaccines. He had not seen a fatal case, but he had seen two cases which were so nearly fatal as to necessitate a warning when speaking upon the subject of polyneuritis.

Professor EDWIN BRIMWELL (Edinburgh) emphasized that in many cases of multiple neuritis the etiology was most obscure, and in a considerable proportion it was impossible to find the cause. He believed that more than one factor might be active—for example, influenza might determine the onset of palsy in a victim of lead poisoning. Professor Brimwell also drew attention to the occurrence of polyneuritis in association with hyperemesis gravidarum, and described a case he had recently met with. In addition to the usual signs of multiple neuritis, the patient also showed nystagmus, aphonia, bilateral facial paralysis, and Korsakoff's psychosis. In the etiology of some obscure cases of polyneuritis, was it possible that a food factor—a deficiency of vitamins—might be of etiological moment?

The President (Sir MORRIS CHUTE) ventured to think that if this subject were discussed again, as it no doubt would be, in some years' time the mental aspect would take a much larger place in such a discuss. The influence of poisons and toxæmia upon the mental state of the patient was becoming increasingly interesting to him, as

it must be to anyone whose work lay in psychological medicine. He referred not so much to the more gross forms of poison, which could be, and not infrequently were, detected by simple means, but to those toxins which were of a much more subtle character. In the meanwhile he appealed to those neurologists who worked in the general hospitals to observe any minor mental changes in patients who were suffering from the conditions which they had had under discussion. It was the early minor mental changes, if any were found, that would have a double value from the psychiatric side, for they would indicate the order of failure, and in this way point to the most likely methods of avoiding the development of the more serious symptoms. Sir Maurice had always felt the importance of fitting states in exposing the patient to the danger of infection. They had heard during the discussion how selective some of these poisons were, and he had listened with great interest to the remarks on this point, as he had long appreciated that it was a certain type of nervous system which was more prone to suffer when exposed to toxic elements. Dr KUMNER WILSON had objected to Dr Johnson's example of much fatigue on the ground that the flexor muscles of the arm should fatigue as well as the extensor, but this would by no means follow, as the flexor were the stronger owing to their anatomical advantage.

T. EUSTACE HILL, OBE, MB, President

DISCUSSION ON INFLUENCE OF SUNLIGHT AND ARTIFICIAL LIGHT ON HEALTH

OPENING PAPERS

I.—J. O. AND HILL, MB, I. R. S.

(From the National Institute for Medical Research.)

RADIATION, according to modern theory, is a phenomenon arising from changes in the position of electrons which fly round the central nucleus of each atom in a variety of orbits. When radiation is absorbed by an atom certain electrons are moved from inner to outer orbits, and radiation must be absorbed in certain well defined quanta to effect this change. When electrons pass from outer to inner orbits radiation is emitted, this change can be brought about in atoms by electrical energy, by heat, or by chemical reactions of molecules, which are, however, probably in all cases started by radiation.

Radiation is a vibration transmitted with the velocity of light and differing in kind according to wave length. Thus the Hertzian waves used in radio-telegraphy have wave lengths hundreds of metres long. The shortest of these merge into the infra-red 60,000 to 760 μ or dark heat rays found beyond the red end of the spectrum ($\mu = 1/1,000,000$ millimetric).

The visible rays have wave lengths from 760 to 400 μ , extending from red through orange, yellow, green, blue, to violet. Beyond the violet end of the spectrum, if a rock crystal or quartz prism be used, extend the ultra-violet from 400 to 180 μ . A glass prism absorbs all except the longest of these, all rays shorter than 330, and absorbs those shorter than 185 μ .

Beyond the shortest known ultra-violet rays (about 100 μ) come the softest x-rays, and these merge into hard x-rays and gamma rays with wave-lengths shortening to 0.01 μ . To have any action rays must be absorbed. For example, the visible rays pass through the transparent media of the eye and are absorbed by the retina, and it is on the retina that they have action resulting in excitation of the optic nerves and in turn of the visual centres in the brain.

The Hertzian waves have no effect upon us until transformed by special apparatus into auditory waves. The dark heat waves are readily absorbed by water and warm the surface layer of the body, penetrating less deeply than the visible rays, many of which pass through the epidermis and warm the blood in the dermis, the red rays even penetrating to and warming the subcutaneous tissues, such as the more superficial muscle.

The eyes have been evolved with transparent media and retinae sensitive to visible rays so as to secure acute sensibility to changes in the environment, recognition of food and injurious substances, of friend, mate, and enemy. Of the ultra-violet rays we have no sense, and have to use special means such as quartz prisms and fluorescing screens, or photographic films, to make evident their spectrum. These rays have very little power of penetration and are absorbed largely by the epidermis, the longer ones only passing through with the visible rays to be absorbed by the blood beneath. The shorter ones are absorbed by the horny surface layer of the epidermis and so have no effect on the deeper lying living cells. The middle ultra-violet rays act on these, and if intense in energy value kill the cells and produce "sunburn." Here is the experimental proof of these statements.

A powerful long flame arc is focused by means of a large quartz lens the central part covered with a disc of black paper. The ultra-violet rays being shorter in wave length are more refracted and come to focus a little nearer to the lens than the visible rays. Let the beam of light from the arc pass through a chamber with parallel sides of quartz (rock crystal) filled with distilled water to cut out heat rays and let the focus be brought on to an area of white skin and the skin be irrigated with cold water to prevent burning by the visible rays. Let the exposure be, say, for two minutes. There follows some few hours later an intense erythema with soreness and still later desquamation.

Substitute a 3 per cent quinine solution for the distilled water and repeat the experiment but let the exposure be, say, for fifteen minutes. Nothing follows. Now a quartz spectrograph shows that the quinine solution takes out all ultra-violet rays shorter than 330 μ . It follows then that the visible and long ultra-violet rays if their heating effect is stopped by irrigation of the skin have in themselves no power to produce erythema. Without cooling the visible rays at once burn the skin. It may here be mentioned that the visible rays allowed to play on the uncooled skin until the point of unbearable burning is produced will heat up the subcutaneous tissue 0.5 mm deep to about 47° C. Dark heat will only raise the temperature correspondingly to 45° C. (Sonne, Argyll Campbell, and L. Hill).

Let us substitute for the quinine solution a saturated solution of uric acid (1 in 40,000). This in a stratum 6 cm broad absorbs all ultra-violet rays shorter than 306 μ (Dhere). A very slight erythema in this case results from a fifteen minutes exposure. For the uric acid let us substitute a saturated xanthin solution which in sufficient depth absorbs all ultra-violet rays shorter than 287 μ . A five minutes' exposure is in this last case followed by an intense erythema.

Using a very powerful spark with cadmium poles and a quartz spectroscope one gets an ultra-violet spectrum visible on a fluorescent screen. There is a well marked band with wave length approximately 275 μ , another 257 μ , another 232 μ . Exposing the white skin of the arm for thirty minutes a slight erythema follows in the region of the 275 and 257 bands but none at 232.

Placing a drop of water containing infusoria in the 275 band one finds the infusoria killed in about thirty minutes in the 232 band in about three minutes. The 232 band then which is far more lethal to microbes has no effect on the skin. This is because it does not penetrate through the horny layer of the skin. The shorter the ultra-violet rays the less transparent is the epidermis to them. A thin film of the horny layer of the skin taken from a desquamating area or the mesentery of a rabbit will prevent most of the active ultra-violet rays passing.

Hausser and Vahler, using a large quartz spectroscope and a mercury vapour lamp, have measured the intensity of various bands with a bi-thermopile. Using equal intensities they found band 297 μ gave a maximal erythema effect, calling this 100, band 313 gave 4.5 per cent, band 302, 58 per cent, band 289, 30 per cent, band 280, 28 per cent, band 265, 19 per cent, and band 253, 16 per cent of the maximal. We see, then, that the ultra-violet rays which act on the skin are restricted between, say, 320 and 240 and far the greatest effect is produced by just those rays which come through with the high sun and clear sky—namely 305 to 295. No rays shorter than 290 are found in the sunlight when examined with optical apparatus and shorter than 280 using a photo-electric cell, for shorter rays are all absorbed in the high regions of the atmosphere.

With arc lamps we have rays as short and shorter than 200 μ but probably none of these shorter than 240 penetrate the horny layer of the skin. The difference between the high clear sun and the arc, then, depends on the presence of shorter rays in the arc—namely, from 290 to 240. To sum up the long ultra-violet rays—for example, longer than 350—penetrate to the blood and are absorbed with the visible rays there and converted into heat, the middle ultra-violet rays penetrate to the deeper living cells of the epidermis, the shorter ultra-violet rays only to the more superficial living cell, while the shortest do not penetrate to these, but are stopped by the horny layer of

the epidermis. It is on the living cells of the epidermis that the ultra-violet rays act. According to modern theory they knock electrons off atoms and alter the electrical charge of the ultra-microscopical particles in the colloidal protoplasm, which results in an aggregation of these particles. There follows chemical (molecular) change which is of such a nature as to provoke, after a latent period of some few hours, erythema, oedema, and lymphoexiosis. Some small portion of the biologically active ultra-violet rays may reach the blood vessels beneath the epidermis and thus act directly on endothelial cells, but most of the effect is undoubtedly indirect and through excitation of chemical changes in the epidermal living cells which, if carried far enough, result in death of these cells and a burn.

The curative effect of the sun on the erythema is undoubtedly can be brought about by exposures short of production of actual erythema, and for general light baths no more than the first degree of erythema should be produced. Given such erythema there results an increase in the haemo-bactericidal power of the blood as tested *in vitro* (Colebrook, Edinow, and L. Hill) which seems to be significant. Such rise can also be produced by heat or a mustard poultice, but only if these agents produce a lasting erythema.

The epidermis offers a vast field of living cells exposed to the insults of the world under the protection of the horny layer. Such insults seem to provoke the immunizing powers, probably through absorption of damaged tissue products, and excitation of reactions in the blood-forming and other organs of the body. Excessive damage and reaction will be harmful, a small amount stimulating and useful. If the body is already fighting an acute disease—for example, active febrile tuberculosis—very great caution must obviously be taken in exposing the skin to ultra-violet rays and the heating effect of visible rays. Reaction from damage to the skin may reduce immunity in such cases, while in chronic infections it increases the immunizing defensive powers and stimulates the function of the body.

Owing to the smoke pollution of the atmosphere in big cities, the ultra-violet rays are cut down by one half and even two thirds in comparison with clean country and seaside places.

A standard acetone methylene blue solution is exposed by us in a standard quartz tube to uninterrupted sky and sunshine during each day, and the fading of the depth of the blue measured against a set of standard blue tubes. The scale of these is biologically standardized. One degree signifies twice to four times as much ultra-violet radiation as is required to produce a slight erythema of average white skin. Skins vary in sensitivity. Smoke pollution cuts out shorter rays, so that fewer rays of greater biological power—namely, those about 300 μ —come through even on sunny days. What with mist, cloud, and smoke, glass windows which cut out rays shorter than about 330 to 320 μ , and clothes, city people get almost no exposure to ultra-violet rays during the winter, and while every effort should be made to prevent the smoke pollution by use of smokeless fuel, and to educate people to expose their skin to the sunlight whenever opportunity occurs, a great deal can be done for the general health by means of arc baths. These should be instituted, not only in hospitals, but in schools and public baths.

A skilled attendant, teacher, or nurse is required to control their use, but they are no more dangerous than a public swimming bath. Given a long flame arc, 1½ to 3 kilowatts, with "white flame" carbon poles, and a wire net screen a yard away from it, children can dance within one or two yards of such safely for five minutes under save for a loom cloth. As acclimatization comes on and the skin browns, the time can be lengthened to ten or fifteen minutes. Such baths once or twice a week would, I believe, do much to maintain good health and prevent diseases such as tuberculosis, rheumatic fever, skin diseases, lesser catarrhs, etc. By using tungsten cored carbons in place of "white flame" the ultra-violet intensity is greatly increased, and the above exposure times could be reduced to one quarter, or even less. Coggles or screens for the eyes must, of course, be worn to prevent conjunctivitis.

A great many lamps are at present on the market many of which are so weak in respect of ultra-violet radiation as to

be of little use. Some arc quartz instruments giving only violet light. At the Finsen Institute lamps are used which are relatively weak, in comparison with long flame arcs, in ultra-violet rays and which in visible and heat rays, and exposures as long as two hours are given in shut-up rooms where the patients sweat profusely. We have secured excellent curative effects from short exposures to long flame arcs powerful in ultra-violet rays, and obviously there is great economy in these short exposures. The ultra-violet ray intensity depends on the temperature of the arc and the nature of the pole. The carbon poles should be not too thick and should contain a suitable metal core, and the energy put through the poles should be sufficient—for example, 2½ to 3 kilowatts for "white flame" carbon arcs, the core of these contains aluminum and magnesium. Using tungsten-coated carbon poles arc lamps taking much smaller amounts of energy suffice, but tungsten is expensive. With "white flame" carbons and the long flame arc taking 2½ to 3 kilowatts, half a dozen patients can sit around and be treated for five minutes on the front and five minutes on the back of their bodies. Using two such lamps in series and the patient being between the two lamps, the whole body can be treated at once in five minutes. With a 220 volt current and each lamp taking about 100 volts and 30 amperes, this is the best arrangement. These lamps are made equally good for alternating or direct current.

The sensitivity of new patients can be tested by putting a cuff round the arm and exposing an area of skin through a hole in it for five and another for ten minutes, and seeing the resulting degree of erythema next day. Only the first or very slight degree of erythema should be produced. The exposure can be lengthened gradually to fifteen minutes, and, finally, if the case is resistant to the curative influence, tungsten coated carbons may be brought into play when the skin has become hardened to "white flame" carbons. For lupus a local treatment of the nodules with a water cooled mercury vapour lamp accelerates the rate of cure produced by the general light baths. Ultra-violet radiation puts up the general resistance of the body to disease, and promotes good health and sexual power of citizens who by sedentary indoor lives during the winter have become depressed and out of condition. Such baths have power to cure in many cases skin diseases which prove resistant to other methods of treatment, such as ichthyosis, psoriasis, eczema, and boils. They help many chronic infections and anemias resulting therefrom—thus, for example, arthritis, chronic bronchitis, and colitis may be relieved. Marasmus and delicate children may be made better, and mothers who cannot nurse their babies may be made more efficient. The general arc bath affords a natural, simple, and valuable stimulant of the health functions of the body. It is possible that the increase of cancer is associated with sunless conditions of life. Protection of rabbits against inoculation of a malignant tumour has been obtained by keeping them in cages lit with a mercury vapour lamp (glass bulb) and incandescent filament lamps (Pearce and van Allen).

Downes and Blunt in 1879 showed that the ultra-violet rays kill bacteria. The shorter of the rays are more powerful than the longer. I found that infusoria in a droplet of water were killed in thirty minutes by the 275 band of the endium arc, and in three minutes by the 232 band. As already stated, the shorter rays have very little power of penetration. Mr J E Barnard has found even that one ultraviolet bacterium may screen another, lying beneath it, from these rays. The sterilizing power of the rays, owing to the small penetration, is, then, limited to the surface layer either in case of the skin or of unclean objects. Skin excised from lupus patches just after a local Finsen light treatment and injected into guinea-pigs has infected these animals—the tubercle bacilli were not killed (Jesonek).

Sir Henry Gaurain tells me that he has evidence that radiation of excised bits of lupus skin compressed between quartz may kill the bacilli within them. He thinks that by pressing out the blood in the living skin with a quartz-water-cooled compressor and by repeated radiation the longer ultra-violet rays may reach the bacilli sufficiently to destroy them. They are however, probably destroyed by the inflammatory reactions of the tissues. While the skin is sensitive to the middle ultra-violet rays, infusoria and bacteria exposed in a droplet of water are far more sensitive to the short

ones. Infusoria are, however, also killed by long exposure to the longer rays—for example, those not filtered out by a solution of quinine, and which do not produce erythema on the skin. Sensitivity to longer rays—for example to the visible rays—may be brought about by a titer, such as eosin or hematomorphyrin. After injection of a minute quantity of the latter, severe cutaneous lesions and death result in albino animals on exposure to visible rays. In those rare cases of hydroa aestivale the persons are sensitized by the presence of porphyrin in their blood—in unborn abnormality of a most uncomfortable kind, requiring careful avoidance of bright daylight.

Owing to lack of penetration of any but longer ultra-violet rays through the cornea and lens we must attribute injury to the retina by exposure to excessive light to the visible rays. The conjunctiva is very easily inflamed by the ultra-violet rays. The effect comes on usually at night after first closing the eyes in sleep. Perhaps the secretion of tears and washing of the eye then falls off and the irritation produced by the rays has thus greater play. Melanin—the pigment in the skin—is in particulate form. It is not a sensitizer, but a screen protecting the deeper epidermal cells and the subcutaneous blood. It appears to be a derivative of tyrosine and such like amino acids. By melanin converting the visible into heat rays and warming the epidermis the nerves therein are excited, and sweating and dilatation of the cutaneous vessels provoked together with a diminution of body heat production. The body is thus kept cool by diminished production of heat and increased loss through evaporation, also by increased reflection of rays from the wet surface of the skin. People who pigment well appear to be cured by light treatment more easily than those who do not. Dark-skinned people who freckle only. The latter are biologically more susceptible to tuberculosis. The ultra-violet rays, by acting on the blood spread in a thin film in a rotating quartz flask, not only coagulate some of the proteins but destroy antibodies, antigens, complement factors, hormones, proenzymes, and enzymes. Red cells are protected by the serum from hemolysis, but when suspended in saline they are hemolysed by these rays.

The ultra-violet rays by acting on the skin of an animal have no effect on the content of the blood in specific antigens—for example, typhoid agglutinins or diphtheria antitoxin (Hartley). But the bactericidal power of the blood is put up an hour or two after exposure to the rays when a sufficiently extensive area of erythema is produced (Colebrook Fidinow, and L Hill). By radiation of blood in a quartz flask and the return of this to the animal the haemo-bactericidal power is also put up while that of the irradiated blood itself is destroyed (Fidinow).

The infra-red rays have no bactericidal action other than that due to heat. These heat the surface of the skin mostly. Red rays penetrate much deeper, and may be used to produce the effect of heat (for example, of diphtheria) on mussels, etc. Murray Teich reports good results from red light. Warm visible rays from incandescent lamp are well combined with the cold mercury vapour lamp. Warmth accelerates and cold retards the action of the ultra-violet rays on the skin, but these rays, if intense enough, can burn the cooled skin. They kill bacteria frozen to the temperature of liquid air (Dewar).

Some evidence has been put forward to show that visible rays interfere with the biological action of ultra-violet rays, and some clinicians therefore exclude daylight from arc lamp rooms. Further and more exact experiment has failed to confirm the existence of such interference (Atwell Campbell and L Hill).

It is quite easy by local concentration of an arc, or by a very hot sun, to heat parts of the body—for example, the head—to a high febrile temperature. Exposure in sun boxes or under glass may easily heat up the whole body. Overheating should be most carefully avoided. Cool open air and sun are good, hot midday sun bad, for the treatment of surgical tuberculosis, as Rollier has found in the Alps. Chronic phthisis cases must be protected from heat and given exposure to cool morning sun or arc lamps in cool places. Active febrile cases should be treated by light with very great caution, by minimal doses—for example, sky shine, not sun—and by exposure to cool air on verandas. Cases of arthritis, on the other hand, may be benefited by

heat and ultra-violet rays together. Wounds and fevers do wonderfully well out of doors, as shown by war experience, and all hospitals should no longer be brick buildings, but bungalows with open air wards, verandahs, and unroofed open-air courts about which the beds can be run according to weather. To build new brick hospitals in cities on the old plan is out of date and unjustifiable. We must teach people to get rid of smoke pollution, wear less clothes, and expose more of their skin to light, and then, with the help of arc baths and more playing fields, we can improve health a great deal in spite of the thousands of miles of mean streets which cover our manufacturing districts. Girls by wearing low open-necked blouses and short skirts with artificial silk stockings secure more ultra-violet rays. Men might well alter their dress and get rid of the close collar and long trousers. While exposure of the lower part of the leg to light and cool air has proved to be a preventive of varicose veins, overexposure in cold winter weather alternating with heat of fires may produce a kind of chilblain-like erythema. Physiological knowledge as well as fashion should rule dress, and prevent both over- and under-exposure.

Immunity to ultra-violet radiation is set up in the epidermis by one exposure to a subsequent one, before pigment is formed (Perthes). Thus if the area of the skin be exposed for five minutes, and again for five minutes some hours later and a second area be given ten minutes all at one time, the erythema will be much more marked in the second area. Choosing a small dose, a second one given a few hours later increases erythema and soreness. Maximal erythema, of course, cannot be further increased by a second dose, but this seems to be true for soreness also. The immunity is due, I think, to coagulation of the outer layer of living cells, whence comes peeling. When pigmentation is still well marked weeks after an exposure, susceptibility of the epidermis may be shown to have returned by the erythema following a further dose of ultra-violet rays.

The defective calcification of the growing bones in rickets results from a diet deficient in antirachitic substance and lack of ultra-violet rays. If young rats are put on a diet deficient in antirachitic substance and having a minimum of salts of phosphorus the latter is not absorbed from the gut. Either the addition of antirachitic substance in cod liver oil or ultraviolet radiation for a few minutes a day will wholly stop rickets developing, and cause a minimum amount of phosphorus in the diet to be absorbed and utilized in bone building (A. Webster). It has been proved that the antirachitic substance present in cod liver oil is not vitamin A, and that it can be put into an inactive food by ultra-violet radiation (Hess, Steenbock). Oils retain the required antirachitic power for months. It has been claimed that "active" food substance on oxidation gives off ultra-violet rays but this is not so. The error has arisen through the fluorescence of certain quartz screens used in the photographic tests (A. Webster). The antirachitic substance is produced by radiation of cholesterol or a vegetable sterol (Steenbock, Hess, Dunnington).

We have no evidence so far that radiation can endow an inactive food with the growth qualities pertaining to vitamin A. If this prove possible, the margarine makers will have found a fresh source of fortune in being able to claim that their product is made equal to butter. Rickets can be prevented by making the diet more adequate—for example, by cod liver oil—and also by teaching mothers the need of exposing infants' and children's bodies to the sunlight, and by the use of artificial sunbaths at infant welfare centres. Ultra-violet rays improve the growth and breeding power of fowls. Acting directly on embryos they produce monsters. The loss of breeding power in man and domestic animals such as cattle and tuberculosis in cattle as well as in men are probably due largely to indoor life.

A distinction is made by several writers between "biotic" and "abiotic" ultra-violet rays—those which are beneficial and those which are harmful or lethal. This distinction is I think an artificial one. Any ultra-violet rays, even those longer than 330 mμ of sufficient intensity and acting for sufficient time will destroy infusoria. If the intensity is too weak the amount of energy required to displace electrons and start secondary chemical change either does not suffice or the process of building up

in the protoplasm suffices to balance the process of breaking down induced by the feeble ultra-violet radiation. It is easy to arrange the intensity just so that no effect is produced on infusoria or the skin. In the case of the skin short ultra-violet rays have no effect because of the screening effect due to absorption by the horny layers of the epidermis. It is this which limits the erythema-producing rays to a special part—namely, from about 320 to 240 mμ. Whatever part of the ultra-violet spectrum be used, the biological effect, if any, seems to be the same—namely, aggregation of granules in infusoria and erythema production in the case of the skin. The reaction of the skin appears to have the same curative effect however produced by any one of the various lamps which give varying intensity of different wave-lengths—the mercury vapour, the "white flame" carbon arc, the tungsten arc or the tungsten filament incandescent lamp with quartz globe, the last a very weak source, but effectual in very long exposures.

One clinic uses lamps weak in ultra-violet rays and strong in heating effect, and gives very long exposures five days a week. Another uses lamps powerful in ultra-violet rays, and gives very short exposures once or twice a week. One believes in doses which produce a mild erythema, another avoids the production of erythema. One thinks the production of pigment hastens the curative effect, another believes it screens off the radiation and should be avoided. Varied and unstandardized as are at present the methods of treatment, yet all claim that they secure equally good curative effects. The need of the moment then, is to standardize the lamps for treatment and find out the most economical methods of exposure. Dosage can be easily measured by the degree of fading in a given time of a 30 per cent acetone methylene blue solution put in a standard quartz tube and placed at the same distance as the patient from the lamp. To make the 30 per cent solution fade one degree on the scale it takes two to four times the amount of ultra-violet radiation which is required to produce a slight erythema of the average white skin. In the choice of clothing material artificial silk has an advantage in being the most transparent to ultra-violet rays. Any loosely woven garment, such as a zephyr with a large amount of openings in the mesh, lets these rays through, but the artificial silk fibre, being an acetate cellulose product, is more transparent than protein products such as silk or wool fibres. For heliotherapy, then, one layer of an artificial silk zephyr-like material can be worn when modesty requires it but much longer exposures will then be required.

It has been stated that artificial sun treatment cannot approach the real article in curative effect. Our experience, however, has shown us that arc-light baths, properly regulated and accompanied with advice as to position, cool open air, exercise, and diet, can effect cures in London which appear to be no less good than those reported from Alpiro sanatoriums. To eliminate tuberculosis from cattle, just as from human beings the important point is to secure adequate exposure to light and air. The practice followed by many farmers of shutting milch cows up in byres during the winter and limiting ventilation, with the idea of promoting a bigger yield of milk by warmth of the byre, should be prohibited. Cattle might be given arc-light baths in winter no less than children in schools. For cattle it is of no less importance to give food in winter which is rich in fat-soluble vitamin A. Grass fed cattle give milk much richer in this vitamin than cattle fed on dry winter fodder.

II—G. B. DIXON, MRCS, LRCP, LSA,

Medical Superintendent Birmingham City Sanatorium

Those of you who, like myself, are engaged in the treatment of tuberculosis in localities where the sun's rays are only sparingly available, will appreciate the necessity for some form of artificial light as a substitute. Our knowledge of the effects of heliotherapy only serves to emphasize this need. You have doubtless experienced the satisfaction of seeing cases of lupus and of bone, joint, and glandular tuberculosis improve considerably as the result of heliotherapy, practised during a favourable summer, and have perhaps been equally disappointed at the lack of progress or even

retrogression, shown by the same cases during a subsequent prolonged and sunless winter. Fortunately, as a result of the pioneer work undertaken in this country by Professor Leonard Hill, Dr. Sequeira, Sir Henry Grayson, and others, our knowledge of the possibilities of treatment by artificial light has been greatly increased.

Technique

My experience of treatment by means of artificial light has been mostly in connection with tuberculosis, by exposing gradually the whole body to the light from short flame carbon arc lamps, consuming 75 amperes. Our installation includes four of these lamps, two being used in a room. Around each pair of lamps it is possible to treat from six to eight ambulatory patients, or two or three recumbent patients. The initial dose, which is determined after exposing small areas of the skin, for varying times, and noting the reaction, is evidenced by the presence of erythema, is usually from ten to fifteen minutes.

Treatment is commenced by exposing the different limbs, and then various aspects of the trunk, until the whole body has been exposed. A complete exposure of the whole body is usually attained in four or five sittings. Our patients wear wooden pattens, a loin cloth, and either an eye shade or goggles. Irradiation is given usually on alternate days, and a maximum dose of two or two and a half hours may be eventually given with this type of lamp. After irradiation our patients take a shower bath and have a rub down. Many of those attending for "light" treatment are outpatients, and in spite of the fact that they are receiving treatment in a warm atmosphere for two hours, or two and a half hours in some instances, the occurrence of so called "chills and colds" is rare, even during the winter months.

Pigmentation

Pigmentation, which varies in different individuals, is said to be a guide as to progress and prognosis, it has been stated, too, that the degree of pigmentation is proportionate to the gain in the patient's power of resistance to disease, and has some rough ratio to his progress towards recovery. Whether this is so in every case is doubtful. A certain percentage of patients exposed do not pigment, although their lesion shows progressive though slower improvement than occurs in those who pigment well.

In the use of the general (carbon arc) light (short flame) bath for tuberculous lesions, I would not personally in every case discontinue irradiation because of non-pigmentation alone, if the lesion were showing definite progress and the general condition and tone of the patient improving. Non-pigmenters certainly require more than the usual care in treatment, and the period of exposure must be less than for those who do pigment, if burning is to be avoided.

Pigmentation has been regarded as an autogenous method of protection, and where it occurs satisfactorily increase in exposures may be more frequent, and a longer maximum exposure may be given than should be attempted in the case of non-pigmenters.

Type of Cases Treated

Opportunity is afforded in sanatorium and tuberculosis clinic work for the treatment of most varieties of tuberculosis, and in the light department we have treated cases of lupus, adenitis, tuberculous laryngitis, bone and joint tuberculosis, and a few uncomplicated and also associated cases of pulmonary tuberculosis.

Cases of lupus vulgaris in the majority of instances do well, and, like all other tuberculous lesions, the earlier they come under light treatment the better the prospects of recovery. Dr. Sequeira, who has had extensive experience in the treatment of this type of case by the carbon arc light bath, claims 70 per cent of permanent cures. Dr. Revn of the Finsen Institute advocates the use of local light treatment, combined with the light bath, and claims 96 per cent of cures as a result.

Results from the treatment of cervical adenitis by the light bath are also good. After an initial and temporary increase in size, many glands become gradually less, and harder, possibly as a result of absorption and fibrosis. On the other hand, large indurated and adherent glands

may break down and fluctuate, aspiration and a continuance of light treatment generally giving satisfactory results. The lupoid condition of scars resulting from the breaking down or incision of cervical glands is usually greatly benefited by the light bath.

In many children suffering from the different forms of non-pulmonary tuberculosis, enlargement of the tracheo-bronchial glands can readily be demonstrated by radiographic examination, and in a certain number of these cases treatment by means of artificial light associated with sanatorium treatment results in the disappearance or a diminution in the size and number of the glands, which is a matter of importance in relation to laryngeal tuberculosis. The results of treatment in bone and joint tuberculosis by means of the general light bath are good, particularly in children, when treatment is undertaken before the occurrence of abscess and sinus formation. Tuberculous distichs, and tuberculosis of the carpus, elbow, ankle, and knee joints, I have found to respond well to light treatment.

I have not seen such good results in connection with tuberculosis of the hip and sacro-iliac joints, or in cases of spinal tuberculosis, but in these instances most of my patients have been cases of extensive and long-standing disease, many of them presenting multiple discharging sinuses. Even amongst these there have been some strikingly good results.

A female patient aged 22 who had suffered from tuberculosis of the hip joint for six years in connection with which were five profusely discharging sinuses when first seen was given treatment by the general light bath for nine months. At the end of that time the patient had gained a stone in weight, and there had been no discharge from any of the sinuses for three months. Although there was marked erosion of the bone, and one or two inches of shortening on the affected side, there is now an improvement in the mobility of the joint, and the patient is able to get about on crutches.

An interesting case was that of a child aged 9 years. She was referred to us after having had one arm amputated above the elbow for tuberculous disease of that joint. When I saw her she had tuberculosis in one knee joint, and a tuberculous lesion of the bones of the face which had involved the supramaxillary antrum, from which there were sinuses discharging into the mouth, and externally through the cheek. The child's mental condition was much below the average. After some months treatment in the sanatorium by means of general light baths the sinuses in the face and mouth healed, and the disease in the knee joint became quiescent, pain and wasting of muscles disappeared and mobility almost equal to that in the sound joint was restored. Even more striking was the improvement in her mental condition, she is now apparently a child of good average intelligence.

A fact to be observed in the artificial light treatment of bone and joint tuberculosis is the marked improvement which occurs in the tone of the muscles generally, which, prior to treatment, have been wasted and flabby.

In connection with the artificial light treatment of surgical tuberculosis, it is well to remember that tuberculous abscesses may form in regions where nothing abnormal has been noticed previously. N. P. Ernst calls attention to this, and records the fact that he has observed fresh cases of tuberculosis of the joints occur in patients who were having light bath treatment, there being no previous evidence of disease.

Treatment for tuberculosis of the larynx has been systematically carried out by means of the general light bath (carbon arc) by Dr. Strandberg of the Finsen Institute, Copenhagen, for some years past. He states that, even if combined with no other treatment, it is effective in itself. In many of his cases he uses electro-coagulation simultaneously. By this method he claims cures in about 50 per cent of his cases. When we recall the fact that, excepting tuberculous meningitis, tuberculosis of the larynx is the most fatal complication of pulmonary tuberculosis we have to deal with, Strandberg's figures are startling and encouraging. Many of his patients whom I had an opportunity of seeing were attending the clinic as outpatients, and were exposed to irradiation with a temperature of about 100° F.

In describing the cases of tuberculous laryngitis which he treated, Strandberg emphasizes the fact that these were not cases of simple laryngitis, with congestion only, which frequently occurs amongst those suffering from pulmonary tuberculosis, but were cases showing definite infiltration or ulceration in the larynx. I have treated, so far, a limited number of cases of tuberculosis of the larynx by the general

light bath. The time elapsing since treatment has not been sufficient to allow me to judge whether the resulting improvement is of such permanency as to justify the use of the term "cure."

The results where the associated pulmonary tuberculosis has not been acute, and where the patient's general condition and resistance to the disease were good have been satisfactory. More than one laryngologist who has referred cases to me for treatment has expressed gratification with the results produced. I mention this merely to show that the assessment in most of my laryngeal cases has been made by those who are qualified to speak authoritatively.

One patient, a man aged 36, had suffered from fairly extensive pulmonary tuberculosis for about five years. At the end of this period his larynx showed evidence of tuberculous infiltration with loss of voice. His treatment was supervised by a laryngologist and the electrocautery was used. The patient's disease became progressively worse and the prognosis was serious. He then had a severe and prolonged haemoptysis for which I induced an artificial pneumothorax as an emergency measure about two years ago. After this some improvement occurred as evidenced by loss of fever, diminution in cough and expectoration and slight gain of weight. Following this the patient was given light baths, when a remarkable improvement in his laryngeal and general condition occurred, the improvement in his voice being very noticeable. The artificial pneumothorax is still being maintained, the light treatment continued, and the improvement persists.

An authority of such eminence as Rollier² says that he is convinced that heliotherapy should be a useful factor in the treatment of the great majority of cases of pulmonary tuberculosis, if properly applied. It may well be asked if treatment by artificial light might not therefore be expected to benefit cases of pulmonary tuberculosis. Schmidt,⁴ a Danish worker, considers that pulmonary tuberculosis remains unchanged as a result of light treatment, whereas Oldenburg⁵ claims to have obtained favourable results.

Personally, I have had only limited opportunities so far of treating this disease. Several of those whose surgical tuberculosis I have treated by means of artificial light have had associated pulmonary tuberculosis in varied pathological stages, such as early infiltration, fibrosis, and cavity formation. In none of these have I seen bad results, either in the form of extension of the disease or in the occurrence of haemoptysis, two ill effects which it has been suggested occur when heliotherapy is utilized.

One of my patients, a nurse suffering from pulmonary tuberculosis with a moderate amount of disease in one side and a small localized apical lesion in the other, failed to do well after twelve months sanatorium treatment and was given light baths with quite good results. There has been an improvement in the physical signs, sputum has almost disappeared, a slight but persistent evening temperature has settled down and her general condition has improved.

Conclusions

The general carbon arc light bath, when judged by results, seems to be a suitable form of light treatment for cases of tuberculosis. The spectrum of this light is said to approach more nearly to that of sunlight than does the spectrum of either the mercury vapour or tungsten arc lamp, which is possibly a recommendation.

It is a type of lamp which, when used with care, is perhaps less likely to produce severe burning and other ill effects than are some of the other lamps.

It is particularly suitable for clinics, hospitals, or institutions where large numbers of patients have to be treated.

The carbon arc lamp has its disadvantages, but what type of lamp has not?

The initial expenditure is large. The heat given off from the lamps necessitates careful ventilation if inconvenience to the patients is to be avoided. Two 75 ampere lamps should be used in a room of not less than sixteen square feet, with a ceiling elevation of twelve and a half or thirteen feet. Windows should be placed at such a level that they are well above the highest point in the range of the lamp's movable adjustment. An electric exhaust fan, placed above the ceiling, in the centre of which there is a piece of metal gauze will be found useful as aid to ventilation.

The length of time occupied in treating patients who are receiving the maximum dosage of two or two and a half hours is not economical. This may possibly be reduced

considerably where the walls of the light bath rooms are treated in such a way, or when reflectors of such materials are used, that the rays we wish to utilize are reflected and not absorbed to such an extent as they are at present.

The cost of current per hour for four lamps consuming 75 amperes I have found to vary between 1s 9d and 1s 10d.

III—DORA C COLEBROOK, M.D., B.S., M.R.C.S., L.R.C.P.

North Islington Infant Welfare Centre

The application of light treatment to welfare work is, I think, a very important subject.

At North Islington, where I have been working since September, I have the great advantages of an excellent organization, a large number of children (1,800 on the books) from whom to draw my material, and the close co-operation of experienced medical officers in charge of the centre clinics. There are also on the premises twelve cots for babies and three beds for nursing mothers with their young babies.

In this paper I shall deal only with artificial light, and with that as carried on during the colder months only. In the warmer days our children are all exposed to open-air sun and shade baths in the garden, and the lamp is seldom used.

The more I hear about light treatment, the more I feel the need for full and full reports of work, for details as to routine followed, lamps used, etc., for dispassionate statements which take into account all the circumstances contributing to the progress of the case, and, perhaps above all, for records of failures and of any untoward symptoms arising during treatment.

I do not propose to submit anything sensational in the way of results, for, though there have been remarkably successful cases, I should not like to describe them here, where you have no opportunity of satisfying yourselves that the success was entirely due to the use of the lamp. I make no claim to lightning cures, but rather to some very satisfactory progress in the attempt to raise the standard of health in those children who have fallen behind, to tide them over critical periods, and to make up to them, in such measure as is in our power, for the light which they lack. I look forward to the extension of the work more and more on the preventive side, to seeing in the department not only the bad cases, but those who are beginning to flag, and even especially those whose home conditions deprive them of the minimum of fresh air, sunshine, and exercise. It is my ambition to irradiate in the winter all available babies born during the summer and autumn months, in the hope that the incidence of rickets in these may be lessened.

In the preventive aspect of light treatment—that is, in welfare centres—certain obvious difficulties, which at times seem almost overwhelming, present themselves: (1) that of securing attendance sufficiently regularly for clinical results or for useful records, (2) that of assessing the influence on the treatment of all the potent factors supplied by the child's environment, and (3) that of getting antagonistic influences removed.

In North Islington we see these difficulties clearly in the case of children suffering from rickets. I should say that we have no facilities for x-raying the children, so that the diagnosis rests on clinical evidence—evidence well known to be controversial and unsatisfactory. I have seen very few cases of acute rickets, though in the chronic cases, which we see in fair numbers, there may be, and often is, an active element. The rickety child is not usually a regular centre baby, it is frequently not brought to the centre at all until the shape of its legs compels the attention of the mother, and even when she does appear she is a bad attender—the circumstances which have contributed to the disease are just the ones that militate against us in our efforts to deal with it. And if this is so in the case of rickets, where regular light treatment is a specific how

much more so is it in cases where its effect is less decisive. Some system of transport would revolutionize the outlook, we are pining for a detachable Ford car and driver.

I am using a long-flame carbon arc lamp. In the few minutes allowed to this paper I cannot go into our methods of administration, which I have described elsewhere.

My patients fall into three categories: (1) nursing mothers whose breast milk is failing, or whose baby, though breast-fed, is not thriving; (2) babies of any age and toddlers up to 2 years who are temporary residents in our wards; and (3) babies and children up to 5 years attending the centre from their own homes.

I consider it to be of the utmost importance that there should be close co-operation between the light department and the other departments of the centre. In our case a ship for the interchange of opinions and criticisms is incorporated with the medical officer's record cards, and a weekly record of light treatment is entered there. By this means I am able to know of any change in general treatment which may have a bearing on the progress of the case, and the centre doctor is able to follow the treatment, and on her side to assess progress. Her opinion is particularly valuable as a check to our perhaps prejudiced impressions.

In my initial records an attempt is made to describe, not only the child's physical and mental state, but the essential factors, as far as we can realize them, of its environment. With a mental picture of these things at the start, one hopes to be able to some extent to prognosticate one's chances of success, or to console oneself for the lack of it. The question of diet and all treatment is left to the centre medical officer, my note merely stating whether cod liver oil is taken, and in what form and quantity. In subsequent records exposure times, weekly weights, and heights are noted, as well as all health incidents whose significance though not apparent at the time, may declare itself later. Lapsed and irregular cases are visited by the visiting nurses, and discharged cases are followed up, so that they may report to me at intervals, for six months. Success or failure depends on our power to impress the mother, and—a far more difficult task—the father too. Prevention may be in itself more easy than cure, but it is far more difficult to demonstrate, and we must admit to many failures to do so. On the other hand, one can hardly realize the tremendous effort which these busy mothers have to make to attend at all. On them, however, as well as on the children, we observe the salutary effects of regular attendance, especially during our sun and shade clinics in the garden, where the practice of hygiene replaces precept.

In final records, where figures are available, I make a general survey of the weights, taking them for a few months before, during, and a few months after treatment. At present I am doubtful as to how much direct effect the light has in the case of the older children.

A clinic dealing with fifteen to twenty children daily, and perhaps four to six mothers on alternate days, seems to absorb a number of workers. In my department though we are well provided for with an efficient full-time nurse and the help of London County Council scholarship pupils, we have a reputation for stealing everybody and everything from the other departments. This I welcome as evidence of our enthusiasm.

In summing up my impressions of results, among successes I put firstly all the smaller babies suffering from simple dietetic troubles, either those in the wards or outside. In the wards, whereas previously improvement in function rather than gain in weight was the rule, now with the added light, after three to six treatments, the gain is steady and often striking, and the babies are noticeably happier and brighter. In some cases I have deliberately left a baby who was not doing well for two, three, or four weeks before I started, and by recording the weights all the time, before as well as during the treatment, I seem to see that the start of improvement is definitely associated with the start of irradiation. This may still be due to coincidence, only a large number of cases will help to establish a conclusion. We have also a very definite impression that in those cases where malnutrition is associated with vomiting the effect of the lamp is quickly to stop the sickness. Plabby, soft babies certainly improve in muscle tone

speedily achieving powers and movements which were long overdue.

The older children attending from outside present a variety of different conditions, and with these in many cases a change of type would almost be involved before one could pronounce a complete success. These children are suffering from general debility and backwardness, catarrhal conditions, restlessness, irritability, sleeplessness, and more or less (which, with all due deference to Dr. Cameron, to whose wise words I owe very much, is all too common among the poor, and even the very poor). The cases of rickets I have already mentioned.

The immediate effect of starting light treatment in the majority of cases is a marked increase in vigour and brightness, this is accompanied in most by greater contentment and better sleep, and in some, though by no means in all, by better appetite. Later, improvement in physique follows on these preliminary manifestations. Children referred for constant colds and chronic coughs respond very differently, doubtless according to their pathological condition, but in some the effect is certainly gratifying, while in others it is disappointing. Chronic glands of the neck have shown little response, even though the general condition may have satisfactorily improved.

In an appreciable number there is at first increase in irritability, which only yields to very small doses very cautiously increased.

Relapses with cessation of treatment are not uncommon. This, however, seems to me to be the natural event substantiating our claim we are only supplying a natural demand—"let there be light"—and in the case of a child of this type one might as well expect a few weeks of light to last it for a year as expect one meal to last it for a month. The lesson I learn from the relapses is that we need light more, and not less.

With the nursing mothers treated so far our results have been very encouraging. Among the 16 who have attended at least eight reasonably consecutive times, with only 4 have we had failures, and I am sure that in the case of 3 of them the lactation had been failing gradually for too long a time, supplementary feeding was established and the baby was determined to take the line of least resistance—namely, the bottle. In most cases, where the mother is sufficiently intelligent and not too overburdened with work, we teach her the use of scales, weighing the baby before and after feeds, so that we may get some idea of quantity during the twenty-four hours. In other cases we are obliged to rely on the evidence of the baby's condition in our judgement of progress. My aim with the mothers as with the children, is to give the shortest possible exposure and series of exposures to produce the effect. Directly the supply seems to be re-established the treatment is stopped, while the mother is kept under observation. If failure again threatens, or if the baby again hesitates in weight another short course is instituted. A few of these mothers are taken for a short time into the wards for rest and education. The helpful influences here tend to obscure the reason under consideration, but I have so far found that a mother who responds well in the wards will again respond if she afterwards lapses when out. I must say the figures are interesting and suggestive.

Even after so short a period of work, I feel satisfied that there is a place for light treatment in our centres, but I have so far no conviction as to the best type of lamp or the best system of dosage to use for the purpose. The excellent results obtained by the use of the very long intensive treatment with the Copenhagen type of installation are well established. Retiring from that the very latest school claims to cure almost anything by almost no exposures. In preventive medicine the former method is impracticable while the latter, in my opinion, must lead to disillusionment and despair.

The urgent need is for exact information which shall lead to the discovery of the most economical lamp that will give the maximum results in the minimum time. For this in all probability, we may have to wait till scientific research has established more exactly the biological action of all the different rays concerned. In welfare centres especially, where we have no opportunity for scientific investigation we look eagerly for help from other workers.

GENERAL DISCUSSION

Dr JOHN BROWN (late M.O.H. Bury) said that in temperate climates flowers, vegetation, and children thrive under substantially identical conditions of sunlight and air. When vegetation was grimy to the touch it was stunted, and children were physically deteriorated. Some of our industrial towns remained virtually under a sunblind, with serious results to health. He believed that the generation of electricity at large centres would make for economy in industry as well as improvement in the public health. The diminished market value of property in the immediate vicinity of gasworks and similar undertakings was a measure of their cost to the public, and this would be saved by placing the power-generating stations of the future at a distance from towns.

Dr EIDMOW (National Institute for Medical Research), who had been closely associated with much of Professor L. Hill's recent work, described the action of ultra-violet radiation on chronic fibroid phthisis and tuberculous adenitis. He was satisfied that one of its effects was to promote calcification in tuberculous lesions. The reaction of the skin and other tissues differed in adults and children, and he considered that in the latter exposures should be very brief.

The PRESIDENT (Dr Eustace Hill) said that Professor Hill's paper had revealed what would have seemed not long ago like a scientific revolution. The great benefits that had already accrued from the application of light, both natural and artificial, were due mainly to the labours of Professor Hill and his colleagues in research. He considered that the Section was to be congratulated in having had the opportunity of listening to an account of his own work from so eminent an authority.

Professor HILL, in replying briefly to the discussion, said he regretted that Dr Eidmow had not referred to the observations he had recently made on the increase of the bactericidal power of the blood as a result of ultra-violet irradiations. This was very marked in certain experimental animals. In human blood the bactericidal power was already high, but it also was increased by irradiation.

During the week the medical officer of health for Bath, Dr J. F. BLACKETT, kindly provided opportunities for members of the Section to visit the various child welfare centres in the city, the school medical department, the municipal fever hospitals, waterworks, sewage disposal works, and the meteorological department.

THE EXTENSOR PLANTAR RESPONSE (BABINSKI'S SIGN) IN THE PRESENCE OF COMA

BY

C. O. HAWTHORNE, M.D. GLASG., F.R.C.P. LOND.,
F.R.F.P.S. GLASG.,

CONSULTING PHYSICIAN, ROYAL WATERLOO HOSPITAL FOR CHILDREN AND
WOMEN, AND HAMPSHIRE AND NORTH WEST LONDON HOSPITAL

THE extensor movement of the great toe in response to plantar stimulation is frequently accepted, and rightly accepted, as a proof of the existence of organic change in the pyramidal tract. There are, however, exceptions to this conclusion, and the recognition of these exceptions has considerable diagnostic importance.

In 1911, in a communication¹ made to the Association of Physicians, I suggested (1) that a unilateral extensor response present in a comatose patient does not necessarily mean an organic lesion, and (2) that coma, however produced, may be sufficient to establish in the nervous system the conditions (whatever these may be) upon which the extensor response potentially depends, and in support of these propositions I quoted certain experiences recorded by various authorities, together with some clinical observations of my own. Since 1911 observations on the plantar reflexes have been multiplied, and among these are cases of coma consequent on various narcotic poisons, not associated with evidences of organic disease but accompanied by an extensor response. For the most part writers have been disposed to suggest that the extensor response in such circumstances is to be explained by a direct and specific action of the toxic agent on the appropriate portion of the central nervous system. In each instance, that is, the coma and the extensor response are placed as separate and independent consequences of the poison—the coma from the action of the poison on the cerebral cortex and the extensor response from some other action of the poison on the part of the nervous apparatus related to the mechanism of the plantar reflex. As, however, the agents or poisons so accused are numerous, and as in some of their properties they differ widely from one another, this hypothesis of direct or specific action may reasonably excite some degree of doubt. In any event, the facts leave room for an alternative suggestion—namely, that the agents concerned produce an extensor response because they produce coma; that is, that coma is the common agency through which they reach the common end. It will be generally accepted that the circumstances in which the extensor response appears include influences that disturb the functional relations normally existing between the cerebral cortex on the one hand and the motor cells of the spinal cord on the other. The

suggestion here made is that coma may be one of these disturbing influences, and that therefore coma *per se* may be sufficient to explain the presence of an extensor response.

It is certain that an extensor response may result from an abnormal functional state existing in the cerebral cortex and unattended by any evidence of organic change either in the cortex itself or in any other part of the nervous system. Such a possibility is illustrated in the occurrence of Babinski's sign as a temporary event after an epileptic or other convulsive seizure. Recently I have seen a young man the victim of severe and periodic attacks of hemianopia associated with homonymous hemianopsia and an extensor response, the visual fields and toe movements becoming normal when the headache ceased. Such an experience may be quoted as a convincing proof of the ability of a pathological state limited to functional disturbance of the cerebral cortex to explain the appearance of an extensor response. But if the functional disturbance of the cortex unannounced by convulsions, or, as just described, by homonymous hemianopsia, may cause an extensor toe movement, it is surely not improbable that the cortical condition unannounced by coma may equally produce this result. And the position is carried a stage further when it is remembered that the extensor response may sometimes be elicited during sleep—for the most part in young children but in occasional instances quite definitely in an individual who has reached maturity. Of particular significance in this respect are some observations made by Kleitman (quoted in a recent paper² by Professor T. R. Elliott and Dr F. M. R. Walshe) to the effect that an extensor response was present in healthy young men during the deep sleep that followed deprivation of sleep for a period of 40 to 110 hours. Between the effect exercised on the rest of the nervous system by the cortical condition existing in deep sleep, and that associated with coma, it is difficult to believe there is any essential difference, and if one is an efficient cause of the extensor response why not the other?

When coma and an extensor response follow the administration of a drug or poison it is of course possible to regard both the one and the other as equally independent and specific results of the drug action. Yet the very number and variety of the agents which have to be included in this group (morphine, hyoscine, sulphonal, veronal, coal gas, trinitrotoluene, chloroform in the delayed form of poisoning) render not unlikely the suggestion that the extensor response which may follow their administration is due to some influence that they share and exercise in common. Coma is such an influence, and as the extensor response is here, in view of recorded recoveries, certainly not due to organic change, it is, in the circumstances, not unreasonable to claim that each of the drug agents

above named produces an extensor response because it establishes a condition of coma, and that in this fashion the normal relations between cerebral cortex and spinal centres are prejudiced.

The position is somewhat less confident when coma and an extensor response appear in the course of a general toxæmia, indeed, short of a complete and microscopic examination of the nervous apparatus, the exclusion of the possibility of organic change can in such circumstances hardly be an unqualified one. Even here, however, there are experiences which suggest that coma may play an important part in determining the extensor response. In this relation may be briefly stated the case (acute atrophy of the liver) of a woman, aged 37, who, as later information showed, had recently been treated by intravenous injections at a hospital clinic. When first seen she was jaundiced and unconscious, and ankle clonus and an extensor response were obtained in each lower limb. After three days the coma disappeared and each plantar response became flexor. It is at least within the limits of the possible that the coma was here the agency responsible for the extensor response. In the paper already quoted Professor F. R. Lillott and Dr F. M. R. Walshe record four cases of hepatic atrophy, each patient showing a double extensor response, and they argue that this response in cases of hepatic disease marks the onset of "chocemia." It is noteworthy that in each instance the extensor response appeared only when the patient's consciousness was more or less seriously compromised. The descriptions run (1) "semi comatose double extensor response", (2) "plantar flexor next day mild coma and double extensor response", (3) "plantar flexor next day lethargic with double extensor response", (4) "plantar flexor two days before death coma and an extensor response." Similarly Sir William Willcox in describing cases of icterus gravis writes (1) "comatose extensor plantar response", (2) "comatose in morning extensor plantar reflex 10 p.m.", (3) "unconscious in evening ankle clonus and extensor plantar reflexes present." These experiences obviously are not inconsistent with the suggestion that coma due to hepatic disease, even as coma due to other causes, may determine an extensor response, and this proposal is strengthened by the record above quoted where on disappearance of the coma the extensor response also disappeared and was succeeded by the ordinary flexor movement.

Another toxic state in which unconsciousness may be associated with the extensor response is uræmia. But the association can hardly be pressed into the present argument, for uræmia is often manifested by convulsive seizures, and these, even as in epilepsy, may explain the extensor movement. Moreover, uræmia may be accompanied by organic changes in the central nervous system, including the pyramidal tracts, so that here also a possible explanation of the extensor response other than coma presents itself.

So far as changes in the pyramidal tract are concerned the toxæmia known as diabetic coma may perhaps stand in much the same position as uræmia. Personally I have recorded a case of diabetes, the patient a child of 3 years, with bilateral extensor response not associated with coma, and the explanation would appear to be either pyramidal degeneration or the re-establishment under some unknown influence of the ordinary infantile extensor movement. In the adult I am able to mention two examples of diabetic coma each with a double extensor response. One, a woman aged 56, brought into hospital in a state of unconsciousness and found to yield a bilateral extensor response, later, glycosuria was discovered, and a history of treatment for diabetes during some five years. At the outset the case was regarded as one of cerebral hemorrhage, but post-mortem examination showed the brain and other organs to be free from obvious disease. Whether there were or were not microscopic changes in the spinal cord must remain an open question, but the record plainly announces that diabetic coma must have a place among the clinical possibilities marked by coma and a double extensor response, and it admits the suggestion that such a response may owe its existence to the presence of coma. For the notes on a second case of this order I am indebted to Dr P. P. Dalton.

The patient, a woman aged 36, had been under treatment for diabetes for some months, when, somewhat suddenly, she became very excited and, later, comatose, there were evidences of acidosis and a bilateral extensor response.

In opposition to all that has here been written it may be said, and said truly, that in many cases of coma the plantar response is not of the extensor type. But this negative admission by no means destroys the positive evidence. The exact mechanism of the extensor response may be outside a confident definition, but it is not difficult to believe that to set it in readiness, some definite degree of adjustment or of maladjustment is required. In sleep, for example, the issue is plainly a matter of degree or measure, not sleep, but a certain depth of sleep, is essential to the extensor response. Such a consideration must apply equally to coma, and indeed with greater force, for coma varies not only in its degree but also in its associates, and some of these include agencies that in the highest degree of probability affect widely and in various fashions the several parts of the nervous apparatus, including that (whatever it may be) on which the extensor response directly depends. Hence it is possible to picture a degree or phase of coma which allows a flexor response, or one which decides an extensor movement, or a third, in which the plantar response is altogether abolished. The unquestioned experience that in many cases of coma, in the large majority indeed, the extensor response is not obtained, does not destroy the claim that, given the appropriate conditions, coma may determine this response. Granted a suspension of the cortical functions in the form of a particular degree or depth of sleep and the demonstration is simple, but amidst the conflicts and complications so frequent in clinical cases an experience far from uniform must be judged inevitable. Further, while the extensor response is not always present in coma, neither is it always present in pyramidal disease. Yet no one on this account will deny pyramidal disease to be potentially a cause of the extensor response, and if negative experiences do not exclude the one claim neither can they be quoted as conclusive against the other. The positive evidence broadly presented shows that coma arising in many and varied circumstances and apart from organic disease is, as a matter of confirmed clinical observation, not infrequently associated with an extensor response, and it is on this generalization that the thesis presented in this paper mainly rests.

A few further notes may be permitted. First, while recognizing that an extensor response may occur apart from pyramidal disease, it is well to remember that this response may be the sole objective evidence of such disease, perhaps in an early stage, perhaps for the time being latent. In a series of cases collected to illustrate this proposition I suggested that an investigation of the plantar responses was a necessary part of any satisfactory scheme of clinical examination. Professor Lillott and Dr Walshe think that the "general physician" is in this respect less thorough than the "neurologist," but I hope that few of us come under this reproach. I agree, however, that in so far as we do so we run the risk of serious error.

A second practical point is that when, in testing the plantar reflex, there is so much movement of the foot and toes that it is difficult to be sure whether there is or is not an extensor response, help may be obtained by applying the stimulus along the groove below the external malleolus instead of along the sole. By this method the toe movement may sometimes be obtained free from the confusion which is apt to follow stimulation of the sole in a highly sensitive and explosive patient. It has further been claimed that an extensor response following a stimulus applied below the external malleolus may detect a pyramidal lesion which might escape the test applied in the more usual fashion. Whether this is so or not the method is certainly a useful one, and particularly in the presence of the difficulties and ambiguities just suggested.

As a third memorandum it may be added that an extensor response may be produced voluntarily and for purposes of deception. Some few years ago I was asked to see a man who, after an alleged accident in a railway station, was said to be hemiplegic, incontinent, and unconscious. No signs of injury to the head could be detected,

but the man appeared to be only partly conscious and to be paralysed in his right limbs, and certainly his right pupil was dilated and fixed and his right plantar response was extensor. After some weeks he began to get about in a halting fashion, and in due course he advanced a claim on the railway company. For various reasons this claim was questioned, and an examination in the presence of several practitioners was arranged. At this examination the patient appeared to make two blunders. First, on request, he promptly protruded his tongue, and this with a pronounced deviation, but the deviation was not toward but away from the paralysed limbs. Secondly, he produced unfaithfully a right extensor response, but he did this on the slightest provocation and almost without regard to the site of the stimulus—elf, shin, sole, dorsum, each alike received the characteristic reply. In the first examination the possibility of the man being a malingerer never occurred to me, and the majority of my colleagues at the later consultation concluded that an ingenious patient by the aid of tropine and of some carefully garnered medical knowledge had proved too much for me and for some others equally guileless. Assuming them to be right, I registered a mental note that among the possible causes of an extensor response a place must be found for the deliberate malingerer. Certainly the trick, if once known, is easily repeated, and the experience is worth adding to a list of the circumstances in which an extensor response does not mean organic disease.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

WEBBED HAND WITH ABNORMALITIES
OF BONES

A boy, aged 4, presented webbing of the left hand as to digits 2, 3, 4, and 5. The webs between 3 and 4 and 4 and 5 were complete up to the tip of the nails. That between 2 and 3 was less complete. The palm of the hand appeared long in comparison with the fingers, and only one row of joints distal to the metacarpal phalangeal joints could be made out. X rays showed that one row of phalanges, presumably the middle, was absent. The ossification centres for the metacarpal of the thumb are abnormal. Usually the shaft and head of this bone are developed from a primary centre, while the base has a secondary centre, appearing about the third year. In this respect therefore, ordinarily, metacarpal 1 differs from metacarpals 2, 3, 4, and 5, and resembles the ossification of a phalanx, a circumstance which has given rise to discussion among anatomists as to whether the thumb consists of three phalanges and no metacarpal or one metacarpal and two phalanges. In the present case metacarpal 1 has a primary centre for the shaft and base, and a secondary for the head. Ossification centres are present for os magnum, unciform, cuneiform, semilunar, trapezium, and lower end of radius. As there was no bony fusion between the individual fingers, separation of the soft parts was performed by Didot's method, in two stages. Digits 4 and 5 were first separated, and afterwards 2, 3, and 4. The anatomical and functional results have been good.

ACUTE INTESTINAL OBSTRUCTION DUE TO A GALL
STONE VOLVULUS OF SMALL INTESTINE
ABOVE THE OBSTRUCTION

Impaction of a gall stone is one of the rare causes of acute intestinal obstruction. As the grouping of the symptoms is frequently unusual, the exact diagnosis is often very difficult. It seems right, therefore, to report the following case, which occurred in the practice of the West London Hospital. I am indebted to Mr. Donald Armour for permission to do so.

A woman aged 54 was admitted on May 6th, 1925 complaining of abdominal pain. The pain had come on suddenly three days previously, was colicky, and situated round the umbilicus and in the hypogastrium. Vomiting had commenced shortly after the onset of the pain and had been repeated several times daily. The vomit was at first bilious but had become feculent. Absolute constipation of faeces and flatus had existed from the onset. She had had occasional attacks lasting one to two days of slight epigastric pain, unaccompanied by vomiting for the past seven years, but no symptoms between the attacks. The abdomen was only moderately distended. Coils of gut were visible through the thin abdominal wall, and there was shifting dullness in both flanks. There was no visible peristalsis, tenderness or rigidity. No mass was felt on palpation of the abdomen or on rectal examination. Shock was absent, except for slight lowering of the temperature (97° F) and raising of the pulse rate (100).

I opened the abdomen by a right paramedian incision, its centre opposite the umbilicus. Free serous peritoneal fluid immediately escaped. Distended and congested small intestine was traced to a point 9 inches from the ileo-caecal junction, where a gall stone was found loosely impacted in the gut. The bowel below was pale and collapsed. The loop of ileum immediately above the site of obstruction had undergone axial rotation in a clockwise direction, forming a volvulus with one complete twist, presumably from the irregular muscular movements set up in the intestine by the presence of the gall stone. Owing to the position of the incision examination of the gall bladder region could not be satisfactorily performed. The wall of the gut at the site of impaction of the stone appeared undamaged and the stone was easily displaced upwards. After unwinding the volvulus this was done and the stone removed by opening the bowel. The stone was ovoid 1½ inches long, with a diameter of 1 inch and tuberculated except at its narrow pole which was smooth and presumably had projected into the fistulous communication between the gall bladder and the small intestine which doubtless existed before the stone escaped to bring about the obstruction. The abdominal wound was then closed with a drainage tube to the site of enterotomy.

The patient made an excellent recovery.

N ROSS SMITH, F R C S Eng

ACUTE APPENDICITIS IN THE AGED

The following case seems worth placing on record because of the unusual features which were present.

At 10 a.m. on April 6th I was summoned to a frail old lady, aged 75 who about twelve hours previously, had been seized with vomiting and abdominal pain which had gradually become more severe in the right iliac region.

When I saw her the physical signs were rigidity of the abdomen and pain and tenderness (this last very marked even on gentle palpation) over the appendix area. The temperature was 99.2° and the pulse rate 58. Her normal pulse is 60 and her normal temperature 98°. There were no signs of any external hernial strangulation and the very definite local signs made the diagnosis of acute appendicitis fairly certain.

Dr. Morland Smith saw the patient with me at midday and agreed with the diagnosis and necessity for immediate operation. This was performed in the early afternoon as soon as the patient had been removed to the Southbourne nursing home.

The appendix was found to be very distended and discoloured and tortuous, with commencing ulceration near its base. The usual operation was performed, the appendix removed, and as investigation showed nothing abnormal elsewhere in the abdomen or in the pelvis the wound was closed. Convalescence was uninterrupted and she left the nursing home quite well four weeks later.

The unusual features which make this case interesting were (1) The pulse rate did not increase, and the rise of temperature was negligible. A marked increase in the pulse frequency is often insisted upon as an indication for operation. Possibly the slow pulse and low degree of fever may be explained by the way aged persons react to a toxæmia. (2) The advanced age of the patient, acute appendicitis is rare in patients over 70. When the local signs are definite, to wait for a marked rise of temperature, or an increase in the pulse rate, or to deem the age of the patient as beyond the probability of an acute appendicitis may lead to grave consequences, in this case delay would certainly have been serious. The happy result obtained was due to the speed of the operation (fortunately the absence of any complication assisted in this, because the patient's frail condition demanded quickness), and the careful nursing the patient received.

FREDERICK C FORSTER

Reviews.

THE WAR HISTORY OF THE CANADIAN MEDICAL SERVICES

Two important volumes dealing with the history of the Canadian Medical Services during the great war have been published recently by authority of the Canadian Minister of National Defence. They differ, however, materially from one another in character and in the ground they cover. The first and more comprehensive of the two is by Sir Andrew Macphail, professor of the history of medicine in McGill University, who served first in France, and then with the medical headquarters staff in London. It is the official Canadian medical history of the war, and is the first of a series of volumes now in course of preparation by the historical section of the Canadian General Staff on the history of the Canadian forces during the war. The second of the two volumes is subsidiary to it, is regimental in character, and is restricted more or less to a detailed account of the Canadian Army Medical Corps units with the Canadian Army Corps during the last hundred days of the war. It is written by Colonel Snell, who was Deputy Director of Medical Services of the Army Corps during practically the whole of that period.

The opening chapter of Sir Andrew Macphail's volume discloses his general theme, and indicates the standpoint from which he approached his task. He enters at once, and courageously, into the arena of political controversy. We gather that his main object is to emphasize the lessons that are to be learnt from the difficulties with which the Canadian medical services had to contend in the earlier years of the war because of the failure of the Canadian Minister of Militia to observe the fundamental contrast between the civil and military function or to recognize that the medical service of the army has no existence in itself but is a vital part of a living fabric. Until this lesson was learnt the medical services were the object of unjustifiable attack, for the reason that they were more accessible to criticism than other technical branches of the army. This accessibility of medicine to attack has often, says the author, "proved too strong a temptation for the mingled motives of pride, chagrin, or malice." He develops this theme later in chapters in the middle of his volume, where he enters into a critical account of the origin and results of the bitter political and medical controversy which arose in Canada in 1916, mainly in connection with the attempt then made to segregate the medical services and concentrate the Canadian sick and wounded for treatment in Canadian medical units only. On this subject Sir Andrew Macphail's words do not lack force of expression. He also refers to the conditions created by the hasty preparation of the Canadian expeditionary force in the Valenciennes Camp on the outbreak of war, to the lack of equipment and the supply of unsuitable material such as boots with heels made of paper and wagons of all possible types, "so that each man and every town might have a chance to profit by public funds." Valenciennes was a mistake, Salisbury Plain, where Canadian equipment had to be scrapped and replaced, was the consequence.

Sir Andrew Macphail has purposely avoided writing a chronology of events and personal eulogy of those who took part in them. Consequently he concentrates into less than eighty pages the history of the Canadian medical services from the time they went overseas in 1914 till the close of the fighting on the Ypres front in 1917. The brief account of this long period of trench warfare and the battles of the Somme, the Ypres front, and Vimy Ridge in which the Canadians played so prominent and distinguished a part, is of interest, because of the vivid and picturesque descriptions of the conditions under which the Canadian medical services, in common with all others, lived and worked. The

operations during the advance from Amiens to the Rhine are dealt with in a chapter of some twenty pages at the end of the volume. Between it and the previous operations the author has interpolated chapters on the surgery of the front, on the conditions already referred to, on the diseases of the war, on medical services, on the Red Cross, and on various details, including poison gas, together with brief allusions to Canadian units with the Mediterranean and Siberian military forces, to medical services in Canada, to statistics of establishments, and to mortality and strength, he gives a nominal roll of members of the Canadian medical services who received decorations and of those who were killed in action or died while serving. In the chapters on the surgery and diseases of the war he deals briefly with matters that have already been treated more at length in other publications, but his statements are occasionally sweeping and dogmatic, such as "shell shock is a manifestation of childishness and femininity" against which "there is no remedy," and enteric fever "is about to drop out of the nomenclature of military medicine," the statements are not likely to be generally accepted. A special reference is made to the wide prevalence of "trench mouth" or septic stomatitis, amongst Canadians, but it is scarcely correct to say that it was practically unknown prior to the war. It was fairly common in civil life, although rare in armies.

A chapter of great interest is that on mortality and strength. The number of Canadians admitted to hospital for wounds was 144,656, and for sickness 595,684 equal to admission rates respectively of 245.90 and 945.05 per 1,000 of the strength of the Canadian forces. A table comparing the deaths from wounds and from disease amongst Canadians, Americans and British gives the American deaths from disease as 51,532, in remarkable contrast with 4,660 amongst the Canadians and 32,423 amongst the British. The deaths from battle casualties were 47,940 amongst Americans, 51,678 amongst Canadians and 532,262 amongst British and Dominion troops together. These figures give a percentage of deaths from disease to total deaths of 51.8 amongst American troops, compared with only 8.7 amongst Canadians and 5.7 amongst British combined forces. The strength of the Canadian medical services overseas expanded from 575 officers, 555 nursing sisters, and 3,620 other ranks in 1915, to 1,451 officers, 1,886 nursing sisters, and 12,245 other ranks in 1918. Of these, 30 officers, 21 nursing sisters, and 453 other ranks were killed or died of wounds, and 99 officers, 6 nursing sisters, and 569 other ranks were wounded. The hospital and convalescent hospital accommodation in Canadian units overseas expanded from 3,484 beds in 1915 to 36,609 in 1918, the latter figure being equal to 14.1 per cent of the Canadian strength. In addition, 12,531 beds were provided in Canadian in 65 hospital units.

Sir Andrew Macphail has not entirely escaped the pitfalls that beset the path of the historian, when he states that the casualty clearing station came into being during the South African war, and that at every base hospital there was an annex for the treatment of fractures. But inaccuracies such as these are few and far between and are more than compensated for by the literary excellence and the vigorous style of the author, and the clear-cut lessons he teaches.

Colonel Snell's subsidiary volume calls for little criticism. It is a straightforward and valuable record of the administration and handling of medical units within a corps area of operations and during a war of movement. In a brief introduction to it Major General Fotheringham states that it is full of the kind of experience that will make it valuable, if not exactly as a manual, yet as a source from which tactical and administrative problems can be studied by commanding officers of medical officers. Every army medical officer who makes its acquaintance, as he ought, will endorse these remarks.

The publisher is to be congratulated on the excellent paper, printing, and binding of both volumes. What one misses most are good maps. The official Canadian medical history contains no illustrations, diagrams, or charts, and one map only, a trench map showing the medical situation on the Vimy front in 1917. Colonel Snell's volume has seven maps in a pocket of the cover. They are apparently photographic reproductions of the 1/100,000 black and white General Staff maps, with conventional signs added showing

¹ Official History of the Canadian Forces in the Great War 1914-19. The Medical Services. By Sir Andrew Macphail, OBE, MD, LL.D., etc. Published by authority of the Minister of National Defence under direction of the General Staff. Ottawa: The King's Printer, 1925. (Roy. 8vo. 11 pp. + 428 1 map.)

The C.A.M.C. suggestion, Corps during the Last Hundred Days of the War. By Colonel F. Snell, C.M.G., D.S.O. Published by authority of the Minister of National Defence. Ottawa: The King's Printer, 1925. (Roy. 8vo. 11 pp. + 282 4 diagrams in text.)

the position of medical units. One map, No 6, is photographed down to a small size, the consequent concentration of detail in this map, the dark tone, and absence of distinctive colouring detract from its value. A good key map and sketch maps in the text with less detail would have been easier to follow. The official volume has a good index, Colonel Snell's has none.

In conclusion, it may be said that these two volumes form an important and valuable addition to the medical history of the war, and are a fine record of the splendid courage, intelligent initiative, and untiring devotion to duty of the Canadian medical services.

THE MALARIA TREATMENT OF GENERAL PARALYSIS

The improvement often brought about in patients with chronic mental disorders by various febrile processes was known to Hippocrates, and has frequently been noted since his day. Many essays in the infection therapy of general paralysis of the insane have been made during the last forty years or so, and a general account of the whole subject is given by Dr GERSTMAN in a book dealing with treatment by infection with malaria, his own experience with this treatment begun in 1917, when nine general paralyses were infected with tertian malaria, three by vaccination, and six by the injection of 1 ccm of blood from a malarial patient. One of the nine died early in an epileptiform attack before the treatment was finished. Two were not improved at all by the malaria, four were improved, and three were cured and still remain so ten years later, cured and able to do their work. In 1918 a second series of patients was inoculated with what was believed to be "malaria tertiana"; it proved, however, to be malaria tropica of a pernicious variety, and the result was unfortunately as much as three of the four patients treated died of malarial cachexia in twenty-four, thirty-one and thirty-nine days respectively. In 1919 the treatment was begun again, and since that date has met with an ever-extending application in Vienna.

Discussing the type of case suitable for malaria treatment Gerstman notes that the patients should be in fairly good condition, the presence of syphilitic arthritis is not necessarily a contraindication, as a few juvenile cases are not much benefited by the treatment, whereas a man aged 62 was cured by it. The earlier in the course of the general paralysis the treatment is undertaken the better the result is likely to be, cases with sudden onset and rapid progress are likely to do badly. Great stress is laid on the importance of choosing a pure tertian malaria and not a tropical malaria as the source of infection, it is noted that the infection can be handed on from one paralytic to another experimentally, as a convenient way of transmitting it and that after over a hundred such passages the malarial parasite itself and the type of malarial fever it produces remain quite unchanged. The malaria is transmitted from one patient to another by the subcutaneous injection of from 2 to 4 ccm of blood, taken from a vein in the arm and injected deeply in various directions at a spot under the skin of the back. It is indifferent whether the donor has or has not got fever at the moment; it is important that he should give his blood before he receives his quinine. The incubation period of malaria thus inoculated varies between two and twenty days and is usually from three to eight days. Its onset and course are unlike those of ordinary tertian malaria, and is a rule after four or five attacks of tertian fever it becomes quotidian in type, with the temperature often very high. This fever is very readily controlled by quinine, more so than is malaria occurring naturally, in a general way the drug is given to the paralytic patients after they have had from eight to twelve attacks of fever and it is found that the patient is cured by as little as 7 grams of quinine bisulphate twice a day for three days and then once a day for four days, he is then altogether free from malarial parasites. After this the patients are generally given a course of six neostyram injections (0.3-0.45-0.6 gram) spaced over six weeks.

Many interesting observations made in the course of the extensive treatment of general paralysis by malaria as practised at Vienna, where over a thousand cases have been dealt with, are recorded by the author, and the already extensive literature of the subject is reviewed and quoted. Discussing the form of treatment that employs African recurrent fever (caused by *Spirochaeta duttoni*) in place of malaria, he states that the results in general paralysis and other mental patients are less good, and that the spirochaetal infection is less under control than is the malarial. He lays stress also on the fact that after repeated passages from one human being to another, the malarial parasite changes in such a way that it can no longer be transmitted by the mosquito *Anopheles maculipennis* to human beings. He gives no general statistics as to the percentages of cures and remissions and so forth resulting from the malarial treatment of general paralysis of the insane, but shows good reason for the view that here at last we have a treatment well worth trying in that hitherto incurable disorder.

THE CAUSE OF BILIARY CALCULUS

In 1880 the French surgeon Galippe advanced the theory that all forms of calculus, including biliary calculus, were due to infection. Six years later the view, now so widely held, that biliary calculus were due to infection of the gall bladder was promulgated by the German clinician Nannig. This view has been stoutly combated by Professor ROYING of Copenhagen ever since the year 1899, and his book on the pathogenesis of biliary calculus and the indications for operation on it dated 1924, has recently been translated into French by Dr SAINT-CANE. Professor ROYING argues that biliary calculus are of two kinds, of black calcium salts of biliary acids in the cells of the liver. These pass into the bile capillaries, and there form tiny concretions—black, irregular, and pointed. These agglomerate in the gall bladder, or less often in the bile ducts, and increase in size by the deposition of cholesterol, lime salts of bilirubin and bile acids, and a cement of mixed epithelial cells, fibrous, and blood due to the irritation and tearing of the mucous membrane to which they give rise. They are thus the cause and not the consequence of the infection of the gall bladder and biliary stasis with which they are associated. In the large majority of cases the biliary calculus thus formed remain fixed in the gall bladder, and give rise to no symptoms of disease. If they migrate and cause temporary or permanent occlusion of the cystic duct, the disease of biliary lithiasis appears, with bilious colic, fever, jaundice, and other symptoms of an acute disease that calls for immediate surgical interference.

Professor ROYING writes with clearness and great conviction, and his book is illustrated with two coloured plates of biliary calculus and a photographic plate showing stages in the development of a calculus. He submits the somewhat combative literature of the subject to a critical analysis, and brings forward good evidence in support of his view as to the pathogenesis of biliary calculus. His book may be commended to the attention of pathologists and surgeons interested in cholelithiasis.

FORENSIC MEDICINE

PROFESSOR SYDNEY SMITH's book forms a valuable contribution to the literature on forensic medicine and toxicology. He begins with the signs of death, sudden death from natural causes, and post mortem examination of the body. He has four chapters on different varieties of wounds and two chapters on deaths from asphyxia. The chapter on examination of blood stains deserves special mention because it contains a masterly review of a difficult branch of forensic medicine to which Dr Sydney Smith's researches have made a notable contribution. Impotence, rape, pregnancy, abortion, infanticide, each forms the subject of subsequent chapters. The last quarter of the book is devoted to toxicology, and here the author discusses corrosive

ROYAL BANQUETS IN THE SIXTEENTH CENTURY

It is always interesting to learn how our forefathers lived, and such interest has led to the publication of many old domestic account books of the middle and upper classes, while no doubt there is still more material hidden in country houses which has not yet been published. Some years ago the Jesuit father A. Hamy produced a substantial volume on the interview between Francis I of France and Henry VIII at Boulogne in 1532, in which, among more weighty matters, we to be found lists of the various articles of food provided on that occasion, together with the cost of the whole entertainment on the French side at Boulogne and on the English side during the return visit at Calais. This is not the place to try and unravel the tortuous diplomacy of the time, suffice it to say that neither monarch nor the advisers of either seem to have believed that honesty was the best policy or to have had any idea that the royal word was of value except as a means of deception. According to Pere Hamy, Henry's real motive in seeking this interview was the hope of persuading Francis to use his influence at Rome in favour of the divorce from Queen Catherine. The interview in question cannot be compared in magnificence with that twelve years before on the Field of the Cloth of Gold, but it cost both monarchs a pretty penny nevertheless. In hard cash the Boulogne entertainment seems to have cost 200,000 livres, or £8,000, while the English estimate amounted to £4,053 18s 3d, not including transport. It is clearly impossible to estimate the value of the contributions in kind which certainly formed part of the provision made.

Pere Hamy has availed himself largely of the documents, at that time unpublished, which had been preserved at Longleat by the Marquess of Bath. In these we find detailed bills of fare as follow:

An ordinance for the Kinges highnes and the frensche kinge and their traines at Calais for the space of IIII days

The first Course

Potage
Brawn
Venusonne in breues
Pestells of red doi 1 giosse

Laicke stinte
Venison
Tartre

The occurrence of similar dishes in both courses seems to indicate that that word is not to be given its modern significance but that the second course was a second dinner or supper for those of inferior rank or those for whom there was no room at the first meal.

The meaning of most of these items is obvious, but *leche* is puzzling as it cannot be supposed that any species of Hundo formed an article of diet. The word *brave* gave Pere Hamy a great deal of trouble, but a reference to the *New English Dictionary* shows that it was the name, now obsolete for a small bird of the snipe tribe. In a fifteenth century cookery book we are told "A Biew slew him in the mouth as a curlew." This seems to be a perversion of the celebrated hue recipe and to amount to "Just catch your brewer then slay him!" *Stint*, of course, is a term for sandpipets in general and the dunlin in particular.

Doucette is corn salad. It will be noticed that in these menus there is no mention of beef and only one of "moton," which no doubt means mutton. Perhaps it was thought unnecessary to mention such everyday pieces of resistance. There is little doubt that the national dish was provided, for 1,000 cattle were taken to Calais on this occasion and 300 sheep were killed, as well as 336 does for venison. It is further noticeable that no fish is included in these lists, probably these meals were for ordinary days and fish was reserved for fast days. There was no lack of it, for there is a list of twenty-nine items under this head, from shrimps to seals and porpoises, costing £284 6s. Everything that lived in the water and came on their net was fish for our forefathers, despite the obviously mammalian appearance of the seal.

One is struck by the number of birds which are now not thought worth eating but which were then considered worthy of a king's table. We must confess that we have not experimented with swan, stoik, seagull, or bittern, although we have tasted curlew. Father Hamy tells us, apparently with some feeling, that the bittern is unactable unless it is skinned before being cooked. No mention is made of peacocks—formerly a royal dish. Besides deer the only wild land quadrupeds mentioned are rabbits. Bores, probably wild boars, are, however, referred to. As for dessert, apples, pears, oranges, peaches, medlars, and nuts appear in the provision lists. As it was October it was too late for the softer succulent fruits except grapes.

As a rule the spelling in these accounts does not widely differ from modern practice. There is one interesting instance of phonetic spelling—that is, *saucyges* for "sausages," which shows that the pronunciation of this word has not changed in four hundred years.

The estimate at Calais for wine and beer amounted to £4,800 13s 4d, but we are told that this enormous total was not actually reached. The French account for wine at Boulogne amounted to 68,652 livres, or more than £2,746. It is of interest to note that Francis was accompanied by two doctors (*medecins*). No mention is made of any medical attention upon Henry, but it is very likely that one at least, perhaps Dr. Butts, was with him.

There is much else of general interest in this book, and we cannot take leave of it without remarking on the charming panoramic sketch of Boulogne, with the figure of the artist seated sketching in the foreground, it was drawn by Joachim Deviert in the reign of Henry of Navarre.

The reverend author of this book is not altogether free from the prejudices of a Frenchman and a Jesuit, and Henry emerges from his pages very black indeed, while Francis is most completely whitewashed and appears as an almost saintly character and loyal son of Holy Church.

L. MURKIN LITTLE

THE WORLD EPIDEMIOLOGY OF 1924

THE Health Section of the League of Nations has issued its second annual report on the prevalence of epidemic diseases.¹ The data relate to notifiable diseases in no fewer than 83 countries—29 in Europe, 17 in Africa, 20 in America, 16 in Asia, and Australasia. They may be regarded, therefore, as covering practically the civilized regions of the world, excepting that returns are received from only a small part of South America. Of 42 of the countries, including nearly all the most important, the statistics have been verified by the authorities concerned, and the British Ministry of Health has done this for 24 colonies and protectorates. A result is that some of the totals for the year differ from some of the figures contained in the monthly reports.² The great bulk of the volume consists of statistical tables, in some cases illustrated by maps and diagrams, but interspersed there are many interesting and valuable notes on prevalence. Some of these notes are as follows:

Plague
More cases of plague occurred in 1924 throughout the world than in any of the previous five years this was largely due

MULTIPLE NEURITIS

THE complex subject of multiple neuritis abounds with problems, the solution of many of which remains for the future. The discussion opened by Dr Granger Stewart at the Annual Meeting of the British Medical Association at Bath, and reported fully in our columns this week, serves to restate some of these problems and to summarize the present state of knowledge.

The term 'multiple neuritis' is itself essentially clinical rather than pathological: it represents a syndrome or clinical picture which is more or less characteristic while due to widely differing causes. There would seem to be general agreement that the conception of multiple neuritis must be extended to include a pathological state of the whole of the lower motor neurone, and not its peripheral part alone. In a considerable number of cases of so-called peripheral neuritis the distribution of the motor changes and the absence of sensory loss suggests an implication of the central origins of the motor nerves rather than a truly peripheral lesion, and Dr Kinnier Wilson would prefer to call such cases examples of 'neuritis'. Clinically the cases may be divided into groups which show every gradation between conditions where there is obvious involvement of mixed nerves, as in alcoholic neuritis, and conditions which approximate closely to a pure cell affection, such as acute anterior poliomyelitis. To the latter group belong the cases of acute infective polyneuritis described during the war by Dr Gordon Holmes and Sir John Rose Bradford and Drs Bashford and Wilson. In these cases sensory disturbance was never marked, the main feature following a febrile onset, was flaccid paralysis, starting in the legs and rapidly ascending to involve in succession the trunk muscles and those of the upper limbs and face. The paralysis reached its height within a week, and was accompanied by transient bladder disturbance. In the non-fatal cases slow but ultimately complete recovery followed. Several speakers in the discussion referred to cases of this kind occurring in civil life, and drew attention to their essential similarity to the acute ascending paralysis known for so long under the name of Landry's paralysis. All were agreed that Landry's paralysis ought to be included within the category of toxic polyneuritis in which the brunt of the infection is borne by the more central parts of the lower motor neurones. Acute anterior poliomyelitis itself in its earlier stages is clearly not limited strictly to the anterior horn cells of the spinal cord: subjective sensory symptoms are often severe at the onset, and occasionally there is definite evidence of involvement of the upper motor neurones in the form of transient extensor plantar responses.

While therefore, it is agreed that there is no clear demarcation between lesions affecting the central and peripheral parts of the lower motor neurones, nevertheless it remains to explain why certain poisons exert a selective incidence on the lower motor neurones as a whole and in particular why a general systemic poison should pick out for special attack certain segments or peripheral nerves more than others. As Dr Granger Stewart observed, in some cases the

explanation of this is to be found in a proved chemical affinity between the particular toxin and either the fatty or the protein elements of the nervous tissues, this was demonstrated experimentally by Guillam and Laroche. It is probable, however, that other factors play a part in determining this specific incidence, and reference was made to the interesting observations of Dr F. M. R. Walshe on the local paralyses occurring in diphtheria. In a number of cases of local diphtheritic infection of gunshot wounds he found that the initial paralyses occurred in muscle groups adjacent to the infected wound, while the palatal paralysis seen in faucial diphtheria was absent. At a later stage paralysis of accommodation nearly always occurred, irrespective of the site of the wound, while in some instances a third stage of generalized neuritis appeared. The conclusion seems inevitable that the diphtheritic toxin is conveyed primarily to the nearest parts of the central nervous system, and it is probable that the route of infection is by way of the perineurial lymphatics. That toxins and organisms can reach the central nervous system by this route has already been demonstrated by Drs Orr and Rows. Whether the perineurial infection alone accounts for the wide spread involvement of the nervous system seen in multiple neuritis remains to be decided, while this may be the route in the case of the diphtheritic toxin, infection by the blood stream must often be the more important process. Another possible factor in determining the particular neurones affected in multiple neuritis was referred to by Dr W. Johnson—namely, the influence of fatigue. The late Professor Edinger of Frankfurt laid great stress on this factor in determining the site of toxic lesions, and Dr Johnson found evidence of its influence in cases of lead neuritis. By investigating the type of work performed by men suffering from lead poisoning he was led to conclude that the incidence of the paralysis fell most heavily on the muscles which were in most constant use by the workman. It is clearly desirable that further observations should be made on this possibly important factor.

Certain other points in a long discussion can only be referred to briefly. The well known association with polyneuritis of mental changes, and especially of Korsakoff's psychosis, is not limited to cases of alcoholic neuritis, mental disturbances of this kind are to be referred, as Dr Wilfred Harris pointed out, to a simultaneous affection of cerebral neurones—that is, an encephalitis, and Dr James Collier would include such symptoms in the complete clinical picture of polyneuritis from any cause. Dr F. J. Nattrass and Dr Wooster Drought referred to the rare and obscure cases of recurrent multiple neuritis, in which prolonged attacks of widespread peripheral palsy occur with more or less complete recovery in the intervals. Dr Nattrass mentioned also two cases in which multiple neuritis was accompanied by a uniform enlargement and hardening of the peripheral nerve trunks and cutaneous nerves. Dr A. F. Hurst drew attention to the importance of latent neuritis as evidenced by diminution or loss of tendon reflexes, especially the ankle jerks. In cases of suspected alcoholism strong confirmation of the diagnosis might be obtained if the ankle jerks were found to have disappeared. Similar evidence of latent neuritis was often present in diabetes. Finally, in patients receiving large doses of arsenic Dr Hurst urged the importance of frequent testing of the ankle jerks, as the disappearance of these always preceded, in his experience, the occurrence of obvious symptoms of multiple neuritis.

MENTAL DEFECTIVES IN NEW ZEALAND

RATHER more than a year ago the Minister of Health of New Zealand appointed a committee to inquire into the questions of mental defectives and sexual offenders in that dominion. The committee included, as medical members, Sir Donald McGavin, Director General of Medical Services, Defence Department, Sir F. Truby King and Dr. Adair Paterson, of the Department of Health, and Dr. J. S. Elliott, the Chairman of Council of the New Zealand Branch of the British Medical Association. The report of this committee has now been received. In it the committee expresses itself as 'especially grateful to the British Medical Association for its willing co-operation and assistance,' and to Sir George Newman for a valuable memorandum on the care of mental defectives in England and Wales.

The report is an interesting and valuable document, though it does not add materially to the sum of knowledge on the subjects considered. It is, of course, directed primarily to the question of how this knowledge, and the experience of other countries, can best be applied to the circumstances of New Zealand. Though the immediate cause of the setting up of the committee appears to have been the occurrence of a number of sexual offences which had attracted wide spread public notice, and though it seems to have been assumed that there was at least a probable connexion between the two matters which were directly referred to it, the committee at once realized, and expresses quite clearly and emphatically, that the questions of mental deficiency and of sexual offences are 'entirely separate and distinct from each other. It is true that a certain proportion of mental defectives show then lack of self control in regard to sex instincts and functions as in other respects, but it is very far from correct to suppose that all feeble minded persons are sexual offenders, or that all sexual offenders are mentally defective. On the contrary, among sexual offenders of the worst type, those convicted of unnatural offences are occasionally found to be persons possessing intellectual and artistic powers above the average.' This is a fact which might well be borne in mind by certain speakers and writers on the subject in this country. With regard to sexual offenders the two important recommendations of the committee are that sentences passed upon convicted offenders should be of indeterminate duration, and that full provision should be made for examination into the physical and mental condition of accused persons and of prisoners.

It is somewhat surprising to learn from the report that the proportion of mental defectives to the total population is as high in New Zealand as in other countries (2 or 3 per cent), and that so little has yet been done in the dominion to deal with the problems presented by this class. There are two residential schools, providing accommodation for 195 boys and 80 girls, and special classes have been established in connexion with public schools in each of the large centres of population, but such educational provision is even less complete than in England, and there is as yet no special arrangement for the education of epileptic children or for the establishment of special courts for children or juvenile offenders.

The problem of mental deficiency is not merely educational and social, but also racial or eugenic, and it is with this aspect that the report is largely concerned. The question of sterilization is discussed, and reference is made to the admirable pamphlet issued by the Central Association for Mental Welfare on

Sterilization and Mental Deficiency, which we have previously noticed. An important legal opinion on the question of sterilization in this country will be found in the *SUPPLEMENT* of June 27th (p. 286). The report is rather more favourable to sterilization as a preventive measure than is the pamphlet referred to, but it is recognized (1) that anti-social conduct would not be prevented by sterilization, and might even be increased by a false sense of security, (2) that for those who had to be segregated for antisocial conduct sterilization would be unnecessary, (3) that the greater number of mentally defective children are not the offspring of obviously defective parents. The preventive results of sterilization would therefore be very limited, but they might nevertheless be useful if the procedure were restricted to suitable individual cases among such defectives as did not require segregation by reason of their anti-social conduct. The work of the committee should have early and valuable results, and it may be noted that though the report states that New Zealand has now the reputation with the Imperial authorities of being the hardest and most exacting of all Dominions regarding the health and physical fitness of immigrants, it recommends that the requirements should be made more stringent and the supervision even closer.

THE EXTENSOR PLANTAR RESPONSE

EXTENSION of the great toe on stimulation of the sole of the foot, or Babinski's toe phenomenon, has come to be widely recognized as the most important of all indications of disease of the pyramidal system. Since the reflex was first discovered other methods of eliciting it have been described—for example, Oppenheim's reflex is extension of the great toe produced by firm pressure from above downwards just behind the internal border of the tibia, and the same effect, known as Gordon's reflex, is caused in some cases of pyramidal disease by deep pressure between the heads of the gastrocnemii. There are several other methods, each named after its author, but the multiplication of methods is merely confusing unless it is recognized that the end result—extension of the great toe—is common to all, and that each has the same significance—namely, an indication of disordered function of the pyramidal tracts. Further, the upward movement of the hallux under these conditions is invariably accompanied by a contraction of the hamstring muscles of the same limb—that is, a constant part of the reflex is a tendency to withdrawal of the whole limb from the stimulus. The investigations of Marie and Foix, Walshe, Riddoch, and others have shown that the Babinski sign is, in fact, part of a reflex which is analogous to the flexion or withdrawal reflex found so constantly by Sherrington in animals with completely divided spinal cords. This reflex, Sherrington found, could be elicited from a wide area of the limb if the stimulus was of a harmful (nociceptive) character, and this explains the existence of so many different ways of obtaining the reflex in conditions of disease in man. There are grounds for believing that the movement which we call extension of the great toe is physiologically flexion, and it would therefore be more correct to speak of the extensor plantar response, with its associated contraction of the hamstrings, as the flexor reflex of the lower limb. The reflex is normal during the first year of life, but after this age it is an indication of the release of spinal activity from cortical control through disturbance of the pyramidal tracts. In the large majority of cases such disturbance is due to organic disease, but there are certain conditions in which the disturbance may be of a transient nature. Collier pointed out that the sign is constant after severe epileptic fits.

and it is also frequent after uraemic convulsions. A recent paper by Elliott and Walshe deals with its occurrence in other toxic states, and the subject is also reviewed by Walshe in the number of *Medical Science* for July. The sign has been observed in a few cases of strychnine poisoning and of tetanus without loss of consciousness, but it is much more common in association with the state of coma from different causes—for example, in poisoning by sulphonal, morphia, and coal gas. It is found to be specially frequent in the toxic coma due to severe impairment of liver function, and is therefore met with in delayed chloroform poisoning, acute yellow atrophy, severe infective jaundice, and eclampsia. Lastly, the sign is present during deep sleep in a considerable proportion of normal people. In a contribution to our columns this week Dr C. O. Hawthorne discusses the question whether the occurrence of coma is in itself sufficient to account for extensor responses, or whether the various toxins mentioned have some specific effect on the nervous mechanisms concerned. He also records an example of an extensor response in one foot being voluntarily produced by a ringer. These observations do not detract from the value of the sign, but they indicate that in the case of unconscious patients its significance should be interpreted with caution, with very rare exceptions the presence of the sign in a conscious patient means structural disease of the upper motor neurone.

RESEARCH IN FOOT AND MOUTH DISEASE

THE first progress report of the Foot-and-Mouth Disease Research Committee¹ makes somewhat disappointing reading. The committee was appointed in March, 1924, but owing to the illness of the chairman, Sir Charles Sherrington, and the appointment of Sir William Leishman to fill his place, it was not until two months later that it was able to get to work. It has now been in existence for eighteen months. Laboratory work has been conducted almost entirely at the laboratory of the Ministry of Agriculture at Weybridge and at the Lister Institute in London, but it is hoped that in the future other laboratories will take part in the research. The Ministry possesses at Pirbright, near Woking, a cattle-testing station which has been adapted at a comparatively slight cost to form an experimental station for the use of the committee, and here, and only here, will experiments with ruminants and pigs be carried out. Small mammals may be used for research in specially selected laboratories throughout the country, but only under strict conditions laid down by the committee. The Treasury has sanctioned grants amounting to £25,000, but in the event of more being required the committee will "not hesitate to approach the Ministry for a further grant." Apparently the "virus" which destroyed the former committee has been definitely abandoned. We have from time to time detailed the advances which have been made abroad—there have been none of any moment in this country—and readers will find little that is new in the present report. The committee has repeated the work of Frosch and Dahmen (two members journeyed to Germany to study the technique), but, with two possible exceptions, its experiments have been negative. The two apparently successful experiments could also be explained by the survival of minimal amounts of virus rather than by multiplication, and accordingly the committee is in general agreement with the German committee that the claims of these two workers have not been substantiated. The committee has also been unable to concentrate the virus by centrifugalization, and it cannot find any confirmation of Vallee and Carre's

statement that it is fixed by blood cells or bacteria. It has confirmed the belief that the effects of cold on the virus are slight—lymph was found to be still infective after 180 days at 4° to 7° C. Glycerol was confirmed as a good preservative, while the resistance to ethyl alcohol and chloroform was found to be high. The question of plurality of strains of the virus is still being investigated, but the committee inclines to the view that more than one strain exists, a view which we have previously discussed.² One strain was not transmitted to guinea pigs, while the other was, both were transmitted to cattle. The susceptibility of small animals has been carefully considered. Guinea pigs are easily infected with at least one strain of the virus. The symptoms in these animals are very regular, the mortality is low (about 5 per cent), and a high degree of immunity is conferred. Infection experiments with rats showed that these animals were much more refractory, but were not immune. On the other hand, field mice could be infected with great regularity. However, it was found that under laboratory conditions the disease was only very rarely transmitted spontaneously from one small mammal to another. Apart from Professor Bentham's laboratory at Liverpool, research has been entirely confined to the two departments under the control of the committee. Work of such an urgent nature as is the foot-and-mouth disease problem should not be restricted to one group of laboratories, and we feel that every effort should be made to extend the sphere of the research to "external" laboratories. The present lull in the foot-and-mouth epizootic does not mean that all anxiety is at an end. It means that every effort should be intensified to extend our knowledge of the cause and mode of transmission of the disease, so that when it does again become rampant, as it assuredly will, we may be in a very much stronger position to bring it under control.

THE THERAPEUTIC SUBSTANCES ACT, 1925

IN the SUPPLEMENT this week we publish an article summarizing the main provisions of the Therapeutic Substances Act, which received the Royal assent on August 7th, and giving some account of the circumstances that led to the placing, after long delay, of this much needed measure upon the statute book. The object of the Act, in the words of its short title, is to provide for the regulation of the manufacture, sale, and importation of vaccines, sera, and other therapeutic substances. Manufacture or the scheduled substances (and of substances added from time to time by regulations made under the Act) is to be conducted only by persons and on premises specially licensed for the purpose, and under such conditions as may be laid down by the licensing authority. This authority is for England, the Minister of Health, for Scotland, the Secretary of State for Scotland, and for Northern Ireland, the Minister for Home Affairs. The duty of framing regulations under the Act and of securing uniformity of standards is delegated to a Joint Committee consisting of the three authorities named (or deputies appointed by them for the purpose), and acting after consultation with an expert advisory committee. The advisory committee will consist of a chairman appointed by the Minister of Health, and one member each appointed by the Scottish Board of Health, the Minister for Home Affairs of Northern Ireland, the Medical Research Council, the General Medical Council, the British Medical Association, the Council of the Pharmaceutical Society, and the Council of the Institute of Chemists. The work incidental to the determination of the required standards will be carried out in the laboratory of the Medical Research Council and under its direction. All regulations under the Act must be laid before both

¹ Ministry of Agriculture and Fisheries. First Progress Report of the Foot and Mouth Disease Research Committee. 1925. H.M. Stationery Office. Pp. 43 with two plans. 1s. 3d. net.

² BRITISH MEDICAL JOURNAL, July 12th, 1924, p. 116.

Houses of Parliament, and the Act will be brought into operation by Order in Council not earlier than one and not later than two years from its original date. In the meanwhile interest naturally centres upon the duties entrusted to the advisory committee and the Medical Research Council, and it may be hoped that the former will be constituted with a minimum of delay, for there is much preliminary work of the highest importance to be done. The inclusion in the committee of representatives of the British Medical Association, of the Pharmaceutical Society, and of the Institute of Chemistry is, moreover, a useful reminder that the official system outlined in the Act must to no small degree depend for its final efficacy upon the fullest possible development of pharmacology in this country. The work directed by the Medical Research Council must be supplementary to, and not a substitute for, independent research. We have reason to believe that both the Council of the British Medical Association and the Council of the Pharmaceutical Society are fully alive to this aspect of the matter.

QUININE AND QUINIDINE

Clinical Comparisons of Quinine and Quinidine is the ninety-sixth of the series of special reports issued by the Medical Research Council; it gives an account of investigations undertaken to determine the relative efficiency of quinine and quinidine in the treatment of malaria. This work was organized by a special committee consisting of Dr Andrew Balfour, Colonel S. P. James, Major H. W. Acton, and Dr H. H. Dale. At an early stage in the proceedings Major Acton had to return to India, and the other three members are responsible for the report. The committee sent out specially purified samples of quinine and quinidine to eleven centres in different parts of the world, and drew up a schedule of suggestions designed to secure that each patient of two comparable series received one or other of the alkaloids in the same definite dosage, administered by the same technique and at the same intervals. The supplies and forms were sent out two years ago, and five reports have been received, the most complete is that by Dr William Fletcher of the Institute for Medical Research, Kuala Lumpur, Federated Malay States. This report is published in full. The reports altogether deal with about two hundred cases. The chief conclusions drawn by the committee are as follows: "The conclusion that quinidine is at least as efficacious as quinine is suggested by the results submitted by all the observers. Further, there is no clear evidence of any difference between the two alkaloids in toxicity for the patient. This point, therefore, of the practical equivalence of quinine and quinidine as antimalarial agents may be regarded as definitely settled. On the other hand, the reports provide no evidence at all in favour of Acton's suggestion that the curative actions of these alkaloids are specifically different for the different kinds of malarial parasites. The reports deal with mixed groups of cases, and there is no indication whatever of a preferential action of quinine on benign tertian or of quinine on subtertian infections." The committee points out that there is no likelihood with public opinion regarding quinine to any large centres of population, and suggests that the use is even less complete than may limit its use as an antimalarial. The importance of the conclusion is yet no special importance of the conclusion for epileptic children, or for quinine from the position of counts for children or juveniles and tradition have accorded to it. The problem of mental aids. This conclusion is, of educational and social, but also because the combating of it is with this aspect that the edicts is in the main concerned. The question of sterilization largely upon our ability reference is made to the admiral remedy at a cost low by the Central Association for

enough to make it available for the poverty-stricken tropical peoples who are the worst sufferers from the disease. The committee promises further investigation upon the antimalarial action of cinchonine and cinchonidine, and remarks that, if it should be found that these alkaloids also have the same remedial and toxic actions as quinine, then it would be possible to replace quinine by a mixture of the crystallizable cinchona alkaloids, and the problem of cheapening the supply of antimalarial remedies would be greatly simplified.

THE SPAHLINGER TREATMENT IN BOVINE TUBERCULOSIS

The question of bovine tuberculosis is so closely bound up with that of human tuberculosis that any attempt to unravel the mysteries of the disease in cattle must inevitably react on the disease in man. It is therefore of interest to observe that a committee (according to the *Times* of September 3rd) has been formed in Cheshire to test the value of the Spahlinger treatment as applied to cattle. The composition of the committee is peculiar and its origin somewhat obscure. It consists largely of lay persons, together with Sir John McIndoe, principal of the Royal Veterinary College (not of the Royal College of Veterinary Surgeons, as the *Times* has it), and Drs. T. Watts and J. H. Williams, two medical members of Parliament who have abundantly had experience of M. Henri Spahlinger, now at Geneva in June of this year. Apparently a technical subcommittee is to be appointed to supervise the actual work. A vaccine, at present being prepared by M. Spahlinger, is to be injected into a number of calves, which subsequently—together with the controls—will be inoculated with virulent bacilli and at a later date slaughtered. More elaborate experiments are promised for the future. Nine years ago M. Spahlinger vaccinated a number of cattle at Geneva, and it is claimed that such as are still alive are immune to tuberculosis. It is out of a desire to test this statement that the committee has been set up. Many references to the Spahlinger treatment of human tuberculosis have appeared in our columns during the past two or three years. On May 12th, 1923 (p. 830) we published a general review of the position with regard to this method, and on June 2nd, 1923 (p. 938), we gave some further particulars about the various products, classifying them under two headings—vaccines and antisera. There are a considerable number of other vaccines which have been used in recent years, one of the latest being that of Dr Guerin of the Pasteur Institute of Lille; the composition of this is known, and promising results have been recorded. Some of these vaccines might well be tested in this country by some official committee. The great disadvantage of the Spahlinger vaccines and sera is our lack of precise knowledge as to their composition and method of preparation. The treatment may be all that is claimed for it, but it is contrary to the scientific and medical traditions of this country to conduct a critical investigation into what is virtually a secret remedy. Considerable disappointment was felt in many circles at the failure to guarantee a supply of sera and vaccines to conduct an exhaustive test in this country. A satisfactory advance can be made only when the full details of the composition, mode of manufacture, and technique are placed before the scientific world, and are then examined by an impartial committee of bacteriologists and medical men. It is quite possible that the Cheshire committee has in the meanwhile taken a step which may yield fruitful results, but we feel that the wiser course would have been to investigate first of all those vaccines the makers of which have taken the medical and veterinary professions into their confidence.

SCIENCE AND ATHLETICS

AMONG the many papers read at the meeting of the British Association in Southampton few have aroused so much public interest as the presidential address of Professor A. V. Hill in the Section of Physiology on the physiological basis of athletic records. Hitherto athletic events have been recorded solely from a statistical point of view. Professor Hill has endeavoured, in the light of recent developments in the scientific study of muscular effort, to get at the physiological principles that underlie them. Fatigue is, of course, the dominating factor in determining the duration and extent of athletic effort, but only one form of fatigue—the fatigue that results in a short time from extremely violent effort—is as yet susceptible of exact description and measurement. Other forms of fatigue—such as the wear and tear shown by nervous exhaustion, metabolic changes and disturbances, and sleeplessness—are too indefinite and complex to permit of measurement and accurate definition at present. Professor Hill's physiological estimate of muscular effort is based on the three factors of oxygen intake, oxygen requirement, and oxygen reserve, or the amount of oxidation which may be put off until after the exercise and is used in the recovery process. This delayed oxidation is, he says, as important to the muscle as recharging is to an electrical accumulator. But it can be drawn upon to the extent of some 15 litres of oxygen only before complete exhaustion sets in and no further effort is possible. The extent to which it is drawn on is described as the oxygen debt. The maximum oxygen intake for a man of average size is 4 litres a minute, but the oxygen requirement increases rapidly in proportion to the increase in speed, and it is on these factors that an athlete can determine the speed at which he can run in a given time until he is run to a standstill. Professor Hill explains this by taking the case of a man running for fifteen minutes with a maximum oxygen intake of 4 litres a minute and a reserve of 15 litres to draw on. His total available oxygen would be $(4 \times 15) + 15$, or 75 litres, and he would consequently be able to make an effort requiring 5 litres a minute. Similarly, a two-minute effort would have available $(4 \times 2) + 15$, or 23 litres, and this would permit of the still greater effort of 11.5 litres of oxygen a minute. By plotting out athletic records on graphs for running, rowing, swimming, walling, bicycling, and horse-racing to show the relation between speed, time, and distance, and by using the ingenious device of a logarithmic graph to bring distances from 75 yards to 100 miles into the same picture, Professor Hill was able to show how the speed effort was greatest in the short distances and times, the physiological reason for which is to be found in the above illustrations. An interesting point brought out by him was that a uniform speed throughout is the optimum. He explains this by the illustration of a mile run in four and a half minutes at a uniform speed of 6.52 yards a second. The energy expended, on the basis of the energy output being taken as the square of the speed, would be $4\frac{1}{2} \times 6.52^2$, or 191.3 arbitrary units, whereas if 665 of the yards were run at 5 yards a second and 1.096 at 8 yards a second, the time for the mile would still be four and a half minutes, but the energy output would have risen to 201.5 of the arbitrary units. There were several other points of interest in the address, but they did not affect to the same extent the physiological measurement of effort. Women, for example, do not seem to be capable of prolonging their athletic effort to the same degree as men except in swimming, but the oxygen requirement in proportion to speed has not been determined in swimming and the maximum oxygen intake and oxygen debt are not known for certain in the case of women. Athletes are sure to find in this address something which will not only add fresh interest to their efforts, but may

also enable them to beat the records. As the lecturer said in his concluding remarks, physiology can aid the development of athletics as a science and an art, while in the data of athletic records a store of information is available for physiological study. The reward to physiology and athletics is thus reciprocal.

GLASS PARTICLES IN PRESERVED FOODS

It has often been suggested that particles of glass detached from bottles used nowadays for various sorts of preserved foods may produce lesions of the gastro-intestinal tract. The facts brought forward in support of this suggestion have been scanty, and very little has hitherto been known as to the frequency with which glass particles occur, and of their size when present. Tunkard and Stock have contributed to the *Analyst* (August, 1925) a paper giving the results of a long series of observations made independently on the presence of fragments of glass in samples of food they have been called upon to analyse. Both have found them in a considerable number of samples of bottled foods. Both found splinters and minute particles in jams and marmalades. Stock found particles of appreciable size in twenty-nine out of thirty-one specimens of fish and meat pastes, and Tunkard large files and particles of appreciable size in four out of six samples of lemonade crystals and powders. Minute particles were found by both in a number of other preparations, including pickles and sauces. Tunkard found such particles in eight out of twelve specimens, and Stock in nine out of eleven. In commenting upon the results of their observations they say: "At the present time the cheap glass jar has largely ousted the safer but more costly stoneware jar for the packing of jams and similar articles of diet. These glass jars are in some instances faultily made, and contain air bubbles which easily break down when the jar is filled with a hot liquid. We have, during the last four years, come across several samples of 'lemonade crystals' which were appreciably contaminated with glass particles in this way. The bottles showed many air bubbles, some of which readily broke down internally on lightly rubbing with a glass rod. There is no doubt that the common glass jar at present made is often unsuitable for the reception of foods, especially for food such as jam, which is packed in hot. There are, of course, glass jars of superior make, but these are costly and not commonly used. Glass frequently contains lead, arsenic, and boric acid, and glass of this material may yield up any of these constituents, the amount and nature of which will vary with the contained food. Our examinations have revealed the fact that many foods contain also quite appreciable quantities of siliceous matter, some of the particles of which were sharp-edged and pointed. If the quality of the glass containers used for packing many foods to-day can be improved, so as to remove the obvious objections, well and good, if not, it would be better for the purity of our food supply if we could get away from such containers altogether." In concluding their article the authors state that since the vogue for glass jars arose jams and similar products are now almost invariably coloured with a coal-tar dye, whereas formerly they were often prepared without any added colouring matter.

CHILD LIFE

THE annual report of the National Society for the Prevention of Cruelty to Children is entitled *In Enduring Life*. That is the aim of the society's work for the child. There are not a few school medical officers who can testify to the success of the society in securing it for individual children. The report shows that no fewer than 95,512 children were involved in the cases investigated during the year—nearly 1,000 more children than the combined

population of the cathedral cities of York and Winchester. A healthy sign of public interest in child welfare and of confidence in the work of the society is that the proportion of cases reported by the general public was larger than ever before (62.5 per cent), and that discovered by the society's inspectors lower than any previous record. The bulk of the cases were instances of neglect, but prosecutions were fewer, and it is significant that 3,325 parents, on their own initiative, went to the society during the year in the hope of securing advice and direction in the treatment of their children. There was a falling off in the number of cases in which it became necessary to remove children from their parents. This is one of the best tests as to whether life is being made endurable for the child. But there is always conflict between the advocates of reform in the home where the children live and the people who favour the easier plan of removing the children from parental control. The idea that the home is the best and right place for children may be old-fashioned, but it is standing the test of time and of experience. The balance sheet of the society stands at £121,422, and on this there is a deficit of £5,849—thus despite the fact that income had increased by £3,197 and expenditure had gone down by £5,849. The work of the society deserves the support of every lover of children. Its address is Victory House, London, W.C.2

A CLIMATOLOGICAL CONGRESS

THE climatological congress held in Davos from August 17th to 22nd was attended by 500 members from twenty-three nations, including Great Britain, Germany, Austria, Holland, the United States of America, South America, and China. It was initiated by Dr. Vogel-Eisen of Davos, Professor Loewy, director of the new Swiss institute at Davos for the study of physiology of high altitudes and of tuberculosis, and Professor Dorno, director of the Davos Meteorological Institute. Among those present were Dr. Beinhard, who preceded Rollei in applying sun baths to the treatment of tuberculosis and wounds, Professors Abderhalden, Klaus, Biedl, Stadelin, Schloetter, Koranyi, Grünbaum, Lusk, and Asher. Great Britain was represented by Professor Leonard Hill, Dr. King-Brown, Dr. Peckworth, and Dr. Bernard Hudson of Davos. Professor Hellpach, lato candidato for the presidency of the German Republic, and Professor Abderhalden gave public addresses. Professor Dorno, by untiring patience and energy, and the devotion of his private fortune to the purchase and perfection of instruments, has for many years carried on at Davos the study of the heat and light of the sun, the energy of the ultraviolet rays, the cooling and evaporative power of the air on the human body, and the electrical state of the air, and compared high altitudes with other climates. Free railway passes on the Rhätian railway allowed excursions to be taken to St. Moritz and other places in neighbouring valleys. The Davos valley, lying north and south and protected by mountain ranges, experiences little wind, and its altitude ensures cold dry air and abundant sun. Professor Loewy took a party up to a hut adapted for experimental work which has been built at an altitude of about 9,000 feet. He has made the observation that it is much more difficult to get drunk at high altitudes, because the alcohol rapidly evaporates from the lungs owing to the greatly increased ventilation of the lungs and the thin air. He showed, too, how the tremor of the muscles manifest in involuntary movements in newcomers, unacclimated to altitude, is abolished by oxygen. Over fifty papers were read at the congress, and there was an exhibition of apparatus. Hospitality was extended to all those invited to read papers, and enjoyable concerts and conversaziones and a banquet were provided for all the members. At the final meeting a committee, with Dr. Vogel-Eisen as general

secretary, Professor Abderhalden as chairman, and Professor Leonard Hill as the English representative, was appointed to arrange for congresses of biological climatology, to be held every third year in a different country.

Victoria.

[FROM OUR SPECIAL CORRESPONDENT]

OBSTETRICAL RESEARCH

THANKS to the generosity of the Edward Wilson "Argus" Trustees, who have just given a sum of £10,000 for obstetrical research, the Council of the University of Melbourne has been enabled to announce that it is about to appoint a director of obstetrical research, for two years, at a salary of £2,500 per annum. The applicant is to be a legally qualified medical practitioner, and one who can show evidence of an extensive experience of obstetric practice, gained in Australia. The successful candidate will be required to devote the whole of his time to obstetrical research, to make a survey of obstetric work in Victoria, and to carry out investigations which will have as their object the discovery of the causes of maternal mortality and morbidity in the State of Victoria and the promotion of methods for prevention and treatment. The director's inquiry is to include an examination of the methods of teaching obstetrics to medical students and the training of nurses for obstetric work, the conditions of obstetric practice in hospitals and in urban and country districts, and the conditions of post-graduate study and ante-natal work. He is to visit other States of the Commonwealth if such visits will in any way advance his investigations. The university has formed a special committee, representative of the Faculty of Medicine and the Victorian Branch of the British Medical Association, with executive powers to co-operate with and assist the director.

FURTHER ADVANCES IN THE MEDICAL SCHOOL

A few weeks ago the Governor of Victoria, the Earl of Strathmore, opened (unfortunately in the presence of a small audience) the new department of biochemistry and the new library of the Medical School. The notable additions are a further result of the rebuilding of the anatomy department and the evacuation of the buildings formerly used by this department. The upper story of the old anatomy building, formerly employed for practical anatomy and histology, has been completely altered and redesigned for biochemistry, and placed under the charge of Associate Professor Young. At the official opening of this laboratory Professor Young gave an interesting account of the department, its objects and uses to the medical profession. The ground floor of the old anatomy department has also been redesigned, and the greater portion of it transferred to the ever-growing requirements of the Medical School Library, to which all journals have now been transferred. The convenor of the Library Committee, Professor Osborne, briefly described the changes which had been made in the library equipment, and outlined his policy for its future direction.

THE TEACHING OF PATHOLOGY

The chair of pathology has now been taken over by Dr. Peter MacCallum, who arrived in Melbourne from Edinburgh last March. With the object of associating pathology much more closely with clinical practice, Professor MacCallum has been appointed honorary pathologist to the leading clinical hospitals, and the clinical pathologists of these same hospitals have been added to the staff of the university pathology department, in this way there results a much closer liaison between university and hospital. Weekly demonstrations on clinical pathological specimens have been arranged which all members of the medical profession are invited to attend.

MENTAL DEFECTIVES BILL

A bill is to be introduced in the present session of the Victorian Parliament for the notification and segregation of mental defectives, and the Government has announced its intention of securing an adequate amount of land for the purposes of establishing a colony.

Ireland.

MEDICAL REGISTRATION IN THE FREE STATE

AN article giving some account of the present position in regard to medical registration in the Irish Free State appeared last week in the *Educational Number* of the *BRITISH MEDICAL JOURNAL* (September 5th, p. 455). Mr. S. L. Brown, K.C., member of the Free State Senate, and one of the best known lawyers in Ireland, in the course of a recent statement made with regard to the proposed separate *Medical Register* for the Irish Free State, says he greatly regrets the decision of the Government not to renew or make permanent the Medical Act of 1925. It seems, in the opinion of those best able to judge, irreparable injury to the medical schools and incalculable injury to the prospects of all future and many present students in these schools of obtaining employment or advancement in their profession outside the Free State. He does not think that the advantages which a doctor educated in an Irish medical school obtains by registration are generally understood. The right to practise in Great Britain or in any British dominion or colony is not one of them, for the quack without any qualifications can do so, with the same civil and criminal liability for negligence as the registered practitioner. The only legal advantage which the medical practitioner gains by registration is the right to sue for his fees. The real advantages which he gains by registration are the assurance which it gives the public of his professional qualifications and the assistance which it gives him in obtaining professional appointments. In each of these important matters the value of registration on the general *Medical Register*, as distinguished from the Colonial Register, is enormous. It is for this reason that suggestions have been made that, for the purpose of avoiding the serious results of the decision of the Government some arrangement might be entered into between the General Medical Council and the medical schools in the Free State under which it will still be possible for their graduates to obtain admission to the general *Medical Register*. If the Free State Government adheres to its decision, that is the only mode of saving the situation. It is therefore of vital importance. Mr. Brown urges to consider what any such arrangement involves and whether it is practically possible. Assuming that the General Medical Council were willing to enter into such an arrangement, it could only be carried into effect by means of legislation in the British Parliament amending the existing Medical Acts and conferring on the General Medical Council the necessary powers. No bill for this purpose would have any chance of getting on the statute book unless it were introduced, or at least blessed, by the British Government, and no such bill would be introduced or blessed by the British Government unless it had the active approval and support of the Free State Government. The possibility, therefore, of any such arrangement depends in the end on the active co-operation of the Government of the Free State with the British Government and the General Medical Council. Mr. Brown assumes that the Free State Government will be willing to co-operate to this end. If it will do so, the suggested arrangement is, he maintains, at least a possible one. If not, it would be only fun to say so, and to make it clear beyond question that the only refuge of the Free State doctor qualifying after January next will be the Colonial Register. No matter what may be the attitude of the Executive Council towards the suggested arrangement he would very earnestly join in the plea for delay, and for the continuance of the *status quo* by the renewal of the Medical Act of 1925 for some reasonable period. This would give time for due consideration of the whole question which involves more than the fate of Irish medical schools and of the medical profession of Southern Ireland. It would also give the members of the Free State Government an opportunity of ascertaining the real views of the people. If, in the end, they feel justified in adhering to their present intention, the continuance of the existing arrangement would enable some hundreds of students who

entered Irish medical schools in the expectation of gaining admission to the general *Medical Register* to do so before the present system comes to an end.

President Cosgrave's Statement

By invitation, a deputation of the President and Fellows of the Royal College of Physicians of Ireland met the President of the Irish Free State in the Government Buildings on Thursday, September 3rd, to consider a memorandum which they had forwarded to the Government urging the retention of the existing conditions of medical registration in the Free State. Mr. Cosgrave met the deputation most courteously. He stated that the Government had definitely and finally decided to promote a bill in Parliament for the establishment of a Medical Council and *Medical Register* for the Free State. He pointed out that the provisions of his bill had not yet been finally decided upon, and that in the framing of these provisions he was in hopes of obtaining the co-operation and advice of Irish doctors. He stated further that, as soon as the bill had been framed, it was the intention of the Government to approach the British Government with the view of obtaining some form of reciprocity between the two countries, and he believed that he would obtain such a measure of reciprocity as would not endanger the status of persons seeking Irish medical qualifications. The deputation urged that, if the Government was determined to set up a Medical Council and Register in the Free State, the existing conditions should be allowed to continue until such time as that had been accomplished. Mr. Cosgrave was sympathetic towards this view, but he pointed out that any such continuance of the existing conditions would be granted only on the condition that such a continuance was not used for the purpose of delaying the establishment of an Irish Register. If the medical profession was willing to co-operate with him he said he would be willing to meet it otherwise the Government was prepared to go to the country and fight the matter on the hustings. The members of the deputation having thanked the President for receiving them, then withdrew.

VITAL STATISTICS IN NORTHERN IRELAND

During the quarter ending June 30th, 1925 7,414 births were registered in the twenty-seven superintendent registrar's districts of Northern Ireland, this number being equivalent to an annual birth rate of 23.2 per 1,000 of the estimated population. In England and Wales during this quarter the birth rate was 19.4 per 1,000, and in Scotland 22.9. The population of Northern Ireland in the middle of 1925 is estimated as 1,281,000, including the military forces. Deaths in Northern Ireland in the same period numbered 4,913, representing an annual rate of 15.3 per 1,000. The death rate in England and Wales during this quarter was 11.7, and in Scotland 13. The death rate in Northern Ireland was 0.3 below the corresponding quarter in 1924, and 2.2 below the average rate for the second quarters of the years 1915-24. Of the total deaths registered 550 or 11.2 per cent., were uncertified there having been no medical attendant during the last illness and no inquest held.

DOWN DISTRICT LUNATIC ASYLUM

The fifty-fifth annual report of the Down District Lunatic Asylum contains, in addition to the report of the resident medical superintendent (Dr. M. J. Nolan) the report of the Inspector of Lunatics of the Ministry of Home Affairs for Northern Ireland (Dr. N. C. Patrick). Dr. Nolan provides a large number of statistical tables showing the admissions, discharges, ages at death, and dietaries, and his report is illustrated by many excellent photographs. The Inspector's report bears witness generally to the satisfactory condition of the institution the deaths numbered 42, giving a percentage of 5.9 on the daily average number of patients resident, the lowest since the opening of the institution the average cost per head was £58 10s 5d, the farm account showed a profit of £1,633. Dr. Nolan emphasizes the features of treatment adopted—hospitalization, segregation of mental classes, and suitable

occupation and recreation to the widest possible extent. A dentist visits the institution weekly, and he had 264 patients during the year, and performed 1,111 extractions. 31 dentures were provided and numerous minor repairs. Dr. Nolan draws attention to the delay in the consideration of the report of the Conference of the Asylums Committee of Northern Ireland—it reached some very practical conclusions as regards pressing difficulties, yet the Departmental Commission on Local Government Administration in Northern Ireland has issued a set of questions covering much the same ground, and inviting evidence on allied matters. Everyone recognizes the necessity for reform in lunacy laws, and this reform is of interest to all members of the profession, the delay is injurious to the best interests of the patient and the cause of much worry to medical men. The inclusion of the views of the medical superintendents in these annual reports would help to bring home to the profession, and to the public, the advisable lines of advance.

Scotland.

LUNATICS AND MENTAL DEFECTIVES

THE eleventh annual report of the Board of Control for Scotland, dealing with the year 1924, has just been published. The number of insane and mentally defective persons under the supervision of the Board on January 1st, 1925, was 20,850, of whom 18,398 persons were certified insane, an increase of 9 as compared with the previous year. Certified mental defectives had increased from 2,308 to 2,452. During the year 3,176 lunatics were added to the register, 1,541 were discharged and 1,625 died. The percentage ratio of deaths to the average number of patients was 8.9 which was 1.6 per cent lower than the average for the past five years. The proportion of recoveries was 33.4 per cent of the admissions during the year, which was 3.4 per cent above the average of the last five years. During 1924, 431 persons were admitted to asylums as voluntary inmates compared with 381 in the preceding year. The tendency of parish councils to pay the cost of voluntary patients in district asylums has continued to develop, and a number of other parishes have followed the example of parishes in Argyllshire by giving facilities for persons from their districts to enter district asylums voluntarily as rate-aided patients. The practice of placing adult mentally defective persons in asylums still continues, although there are evidences that it is undergoing a change, and it is hoped that the scheme, at present under contemplation, for the establishment of colonies for the adult mental defective will reduce this practice to a minimum. It is pointed out that asylums are tending more and more to become hospitals for the reception for care and treatment of those persons only who having been of normal mentality have become temporarily or permanently abnormal through disorder or disease. On the other hand, institutions for the mentally defective are broadly speaking of an educational nature, intended to develop the limited faculties of the mentally defective to the fullest extent. It is therefore desirable that the two types of institution should be kept separate as far as possible. It is however impossible to draw a hard and fast line between the classes of cases to be admitted to the two types of institution. The increasing prevalence of encephalitis lethargica is instanced as an example of this difficulty. It is often followed by serious mental symptoms when it affects children and produces mental defect and disorder. In this connexion it is suggested that local authorities should have a children's ward attached to the excellent observation wards which have been established in several large cities for cases of incipient mental disorder. The Edinburgh District Board of Control has submitted to the Board plans for a pavilion providing all varieties of hydrotherapy, light treatment, x-ray treatment and ophthalmological and gynaecological departments in its institution at Bangour. The number of typhoid "carriers" traced in Scottish

asylums was 16 in the year of whom 15 were female patients. The danger to the community arising from the carrier is shown by one female "carrier" who was responsible for a hundred cases of enteric fever in the general community before her pathological state was discovered in an asylum. Fifteen "carriers" had typhoid bacilli, while one of the "carriers" had a paratyphoid bacillus. Reference is made to the excellent work done during the past year by the observation wards established in the general hospital at Stobhill and Duke Street, Glasgow, where mental patients are treated for a period not exceeding six months. The general result of this work was that the number of persons treated in these wards was 1,293, of these 500 recovered, 214 improved, 411 were sent to asylums and other institutions, and 91 died. With regard to the statistics of the establishments for lunatics, out of the total number of patients admitted to various institutions 2,707 were pauper patients, which was 152 less than in the preceding year, while 525 were private patients which was 34 less than in the preceding year. The number of patients who had never previously been registered and who were admitted for the first time to establishments for the insane during the year was 2,446, including 2,022 pauper patients and 423 private patients, both these figures showed substantial decreases on the corresponding figures for the previous year. There was considerably less transference of patients from one establishment to another during 1924, the number of patients so transferred having been 294 which was 475 less than in the previous year. Attention is drawn to the increasing number of voluntary patients as compared with certified cases. These are persons who with the sanction of the Board granted on simple application signed by the patient voluntarily enter asylums for treatment of mental disorder and who cannot be detained for more than three days after giving notice of their intention or desire to leave. They are not certified as insane and are not registered as lunatics but a record is made of their names and other particulars. The total number of such persons admitted into asylums during 1924 was 431, and 556 were resident on January 1st 1925. The average number admitted for the ten years 1915-24 was 280. With regard to the distribution of mental defectives, 567 were maintained in certified institutions for adults, 932 in certified institutions for juveniles and 953 in private dwellings, making a total of 2,452.

England and Wales.

THE ORDER OF ST. JOHN OF JERUSALEM AND THE BRITISH RED CROSS SOCIETY

THE wide range of activities of the Joint Council of the Order of St. John of Jerusalem and the British Red Cross Society is well illustrated by the fifth report of the council, which covers the period from April 1st, 1924, to March 31st 1925 and includes ten departmental reports, the reports of the finance committee, and a statement of account. The military hospital for officers department dealt with 21 new cases during the year, making a total of 17,302 as at the beginning of the year, the main work has been in connexion with officers suffering from tuberculosis. Grants are made from a special fund to Ministry of Pensions hospitals and other institutions to provide materials and training for ex-service men confined to bed in hospital, the industries including basket making, leather work, wood carving and glove making. Gifts were sent to 7,221 ex-service patients who were in hospital on Christmas Day, with the intention of providing some of the comforts that would have been available had the men been at home. Approximately 35,000 ex-service patients were taken for drives or conveyed to theatres, concerts and other entertainments during the year, Wembley Exhibition authorities presented 2,200 free tickets, while on Derby day and for the boat race stations were retained for several car loads of these patients. The Emergency Help Committee provided temporary relief to 19,130 men, pending the allocation of pensions. During the year under review over £21,000 of

such advances were refunded by men previously assisted—evidence of the excellent spirit shown by those receiving this help. Wireless apparatus, musical instruments, cinema apparatus, and various kinds of games were provided, the number of grants being 360, and approximately 8,500 ex-service patients benefited from them. The Home Ambulance Committee has now established 341 stations, and 70,532 patients were carried by the ambulances during the year, the service has proved itself specially valuable in rural areas. The mobile x-ray service, the installation of which we announced a year ago, has already proved its usefulness. The car contains a radiographic couch, and a 6-inch induction coil outfit, which is supplied by a 10-hp dynamo, developing a pressure of 125 volts, with a maximum current of 70 amperes. When the apparatus is withdrawn for use the car serves as a dark room and the development of the plates can be at once carried out in it. The apparatus is capable of dealing with all general work necessitating a very short exposure, such as the examination of the chest, it can also be used for the spine and hip, for investigation of the frontal and lateral sinuses, radiography of the urinary tracts, for which special compressors are available, and for affections of the liver and gall bladder. The demand for this mobile x-ray unit is rapidly increasing, both for private patients in their own homes and for work in the smaller hospitals in and round London. A home for ex-officers suffering from advanced tuberculosis has been established in Putney, and accommodates sixteen patients.

ASSOCIATION OF POOR LAW MEDICAL OFFICERS.

At the annual meeting of the Poor Law Medical Officers' Association, held recently in London, the President (Sir Arthur Newsholme) gave an address on "The future of Poor Law medical officers." He felt confident that the members of the association when contemplating forthcoming changes would desire to regard their official future as determinable by what was best for the impoverished poor, with due regard to the conditions of their permanent appointments and pension rights. A duty devolved upon the public of expressing their indebtedness to the district medical officers who for many decades had tended the sick poor in their homes. Invaluable services had in the main been rendered for quite inadequate remuneration, often disgracefully so. There had been a great increase in the work in regard to certification but reduction in the amount of continuous domiciliary attendance. It was not sufficiently recognized to what extent treatment was becoming institutional. He suggested an exhaustive survey of the present institutional treatment, voluntary and official, within each area to ascertain what was the amount, also the amount of provision for each chief class of disease, acute and chronic, mental and other infectious and non-infectious, the arrangement of this provision geographically and in relation to population. The survey should also include an inquiry into the arrangements for specialized diagnosis and treatment of difficult problems and what provision existed for consultations with specialists in difficult cases and the extent of the provision for cases needing operative intervention and the working arrangements, if any, between voluntary and official hospitals when specialized treatment or difficult operations were needed. In regard to the treatment of tuberculosis and venereal disease, with the entire removal of special Poor Law conditions, the available institutional provision for satisfactory treatment could be vastly increased. To those causes of disability and destitution combined remedial and preventive measures could be applied, only possible when those who treated preventable disease were also immediately concerned in the adoption of every practicable measure for its prevention. He was strongly of the opinion that a chief means for securing the needed co-ordination of domiciliary and hospital treatment would be through increased use of nurses, both in hospitals and in the homes of the sick. It was desirable that there should be exact information as to the present amount of such attendance and its character for every union in the country. Such an inquiry would be helpful to county councils and county borough councils when they had added to them the present Poor Law functions. He considered it would be a calamity

if in such transfer two conditions were not fulfilled (1) There should be grateful acknowledgment of the increasingly efficient and valuable work which boards of guardians had done for the helpless poor. (2) The public should realize that although on its medical side this work, for the sake of efficiency and in order to develop its preventive potentialities, must be made part of the work of public health authorities, there would be an irreparable loss in continuity and efficiency unless the workers in present Poor Law administration remained to take an important part in the work of the future.

MENTAL HOSPITALS

Birmingham

The city of Birmingham mental hospitals comprise Winson Green and Rubery Hill and Hollymoor. At the former the recovery rate in 1924 was 45 per cent, calculated on the direct admissions. Almost all the recovered cases had previously been allowed leave of absence on trial before being discharged. The forms of disorder most frequently resulting in recovery were confusional insanity in 51.2 per cent, melancholia in 21.9 per cent, mania in 10.9 per cent, dementing psychosis in 7.3 per cent, and delusional insanity in 6.1 per cent. At Rubery Hill and Hollymoor the recovery rate was 48.6 per cent on direct admissions. Amongst factors militating against successful treatment mention is made of the reluctance of relatives to seek hospital treatment for the patient early enough, and the hindrances to such treatment caused by the necessity of certification. Stress is laid on the importance of discovering and treating chronic septic infections and in this work a staff of consultants is engaged with notable results. Pathological investigations and research work are being carried out under the guidance of Sir Frederick Mott, honorary director of the Joint Board of Research for Mental Diseases of the City and University of Birmingham, reference to which was made in our issue of August 15th (p. 308).

Cardiff

At the City of Cardiff Mental Hospital there were 567 cases resident at the beginning of 1924. The recovery rate calculated on direct admissions was 45 per cent. It is pointed out that too few "first attack" cases are brought early enough for treatment. The hospital has now the advantage of the services of two consultants appointed last year—Dr Gilbert Strickland as psychiatrist and Dr Mason Jones as otolaryngologist. The medical superintendent, Dr Edwin Goodall, referring to the work done in the out-patient clinic for psychiatry at Cardiff Royal Infirmary, mentions the need of an indoor department, as the majority of patients attending for treatment cannot otherwise be satisfactorily dealt with.

Extensive chemical and pathological investigations are being carried out, a report of which has already been sent to the Medical Research Council and will shortly be published. These investigations include blood sugar analysis in epileptics and sugar tolerance tests in epileptics and in cases of general paralysis. A new test for the diagnosis of neurosyphilis, first described by Dr Oswald Boltz of Manhattan State Hospital is being studied and has so far yielded excellent results, the technique being very much simpler than that of the Wassermann test.

Herefordshire

The Hereford County and City Mental Hospital provides accommodation for 535 patients. The number of patients in residence at the beginning of the year was 471. Of the direct admissions 29.6 per cent were discharged recovered. The hospital is entirely free from syphilitic disease during 1924.

Shropshire

At the Salop Mental Hospital there are 786 patients of whom 73 are of the private class. The proportion of recoveries to admissions was 37 per cent. During the past year four patients suffered from typhoid fever all recovered. Only one case of dysentery, a disease which formerly caused much mortality, occurred. Extensive redecoration and improvements have been carried out during the year.

Correspondence.

THE DIVORCE OF SURGERY FROM MEDICINE
 Sir,—In the report of Mr G. E. Gask's paper (British Medical Journal, August 22nd, p. 317) the following passage occurs

The first great division in the profession dates from 1163 and was brought about by Pope Alexander III at the Council of Tours, when an edict was enacted pronouncing that a practice which involved the shedding of blood was incompatible with the holy office of the clergy and forbade them to interfere with any matter of surgery. The effect of this edict was that the practitioners of medicine who then almost all belonged to the clergy, had to abjure manual occupation and to content themselves with syllogisms and inspection of urines.

I confess that this very definite and precise statement surprised me, as it was at variance with my own general impressions. As the writer, however, gives a reference to Sir Thomas Clifford Allbutt—*clarum et venerabile nomen*—my first idea was that he must have strumed or misread what the Regius Professor had stated. A perusal of the original (Clifford Allbutt, *The Historical Relations of Medicine and Surgery*, Macmillan, 1905) negatived that view. Allbutt there (p. 22) says "some fair surgery persisted even in the cloister until it was handed over to the 'secular arm' in 1163", and in a footnote on the same page, after referring to the Councils of Rheims and Lateran, he says "It was at Tours, however, that the sinister and perfidious *Ecclesia* abhorret a sanguine was first pronounced."

As Sir Clifford gives no references in regard to his statements I was forced to look up the original documents. In Labbe and Cossart's monumental work (*Concilia Sacrosancta*, etc., 16 tomes, Paris, 1671) ten canons passed by this council are recorded (tome x, col. 1421) and Martene and Dand, on the basis of two manuscripts, have been able to add twelve additional ones (*Thesaurus Anecdotorum*, etc., tome ii, col. 143). I am not aware if any more authoritative account of the proceedings is to be found elsewhere, but perhaps some of your readers may be able to enlighten students on this point.

I may say, however, that so far as my authorities go there is nothing to warrant Sir Clifford Allbutt's statement. The phrase *Ecclesia abhorret a sanguine* does not occur anywhere, nor any variant or translation of it, nor is surgery mentioned at all. The only canon bearing on the healing art is No. 8, which has the heading "Ut Religiosi Sacerdotes Studia Vitent," and refers to monks and canons regular only, and not to the clergy as a whole. Now, monks were men who had left the affairs of the world and definitely vowed themselves to a cloistered and sequestered life. They were not necessarily priests, probably at that time only a small proportion were ordained. The enclosure of the canons regular was not so strict, but in any case theirs was a community life, and they had deliberately cut themselves off from secular occupations.

Men do not always keep their promises, not even when these take the form of solemn vows. Thus it was found that some of these religious had become barristers or physicians, and were following these professions like lay persons and for gain. The ninth canon of the Lateran Council, 1139, thus refers to them: "*gratia huius avitatio flammis recens neglecta numerum curat pro detestanda pecunia sanitatem pollicentes, humanorum curatores se frequent corporum*" Other councils have a similar tale to tell, so that this state of matters was no new thing in 1163, and the Council of Tours was merely following precedent when it decreed that "no one who has taken vows and made his profession in a religious house shall be permitted to leave his cloister for the purpose of learning to be a barrister or a physician." And the canon ends thus:

If however he leaves his cloister and does not return within two months let him be avoided as if he were an excommunicated person, and if he presumes or attempts to take part in a legal action let him not be listened to, and when he does return he must take the lowest place in choir or chapter or at table and renounce all hope of ever rising to a higher position unless he be so permitted by the clemency of the Apostolic See.

In conclusion it may be noted that this assembly at Tours though attended by some Italian and English

bishops, St Thomas of Canterbury being one, was after all a merely national and not an Occumenical Council. However, a canon, with its thin blooded minority clause, is effective in restraining the monks and canons regular, and not prepared to say. One thing is certain—namely, that for hundreds of years thereafter the ranks of the clergy, what names in surgery belong to the ranks of the clergy. What ever date, therefore, may be chosen to indicate the first great division between medicine and surgery, it is clear that the decree of divorce was not pronounced by Alexander III at the Council of Tours in 1163—1 am, etc., G. MATTHEW GILLES
 Edinburgh Aug 27th

SPECIAL DEPARTMENTS AND MEDICAL EDUCATION

Sir,—Without venturing to give an opinion as to whether the treatment of fractures should be dealt with in a special department or by the general surgeons, I write to put the other side of the general question of which one view is expressed by Professor Cist in his opening paper before the combined Sections of Surgery and Orthopaedic at the Annual Meeting, when he said "I do not think that the [that is, specialists] should have a directive charge of the undergraduate student."

I believe that my aim in the teaching of undergraduate students is the same as that of Professor Gask, being that laid down by Huxley—that we must organize our teaching for the ninety-eight average medical students and not for the two phenomenal ones. To reach this aim, I maintain that the students must come in their undergraduate period under specialists as well as under the general physician and surgeon.

The general principles of the art of medicine are well illustrated by diseases of one special part as they are by that of any other, and therefore "a firm grounding in the fundamentals" can be learnt as well in the special department as they can in the general wards. Taking as instances examples from the part of the body with which I am concerned, the principles of the natural and surgical arrest of hemorrhage can be as well exemplified by operations on the tonsils as by operations done by the general surgeon, and the dangers consequent upon inflammation of bone are more often seen from osteomyelitis of the maxilla process than they are from the same disease of any other bone. When the student goes to each special department after he has done his training in the general ward he has the opportunity there of revising the fundamentals which he has learnt in the general ward.

If the student goes out into the world trained only by general physicians and surgeons, he is very deficient in knowledge of just those diseases of the special parts which it is most important for him to know. Again, taking instance from diseases of the throat and ear, where even the student learns to distinguish the different types of acute inflammation of tonsils and the pharynx except in the throat or patient department? He certainly never learns any of it either in the surgical or medical wards or out patient departments. He acquires a little knowledge of it in his special course at the fever hospital, but he there sees only the cases already diagnosed as suffering from diphtheria, and has no chance of gaining experience in suffering from to whether a patient who first comes up is suffering from this disease or from an acute follicular tonsillitis or other acute inflammation of the pharynx. So also with the ear. When the present regulation that every student before he presents himself for the final examination must have been through our special departments has been given time to take effect, I believe that every practitioner should be—no of them will be—able to examine a dimmied of tonsils whether it is normal or not, and, if it shows signs of acute inflammation, either to incise it himself or to call in someone who is capable of doing so. This "fundamental" principle of treatment of a disease at its earliest stage will only be learnt in the special department, and can never be taught by the general surgeons and physicians.

It is in the special department that we are compensated for that dissociation between general medicine and surgery which Professor Gask so rightly deplors. Although my department is classed as a surgical one there is an

enormous amount of material which passes through it where the patient is treated medically rather than surgically, and a very large number of these patients suffer from the trivial complaints which form a large part of the work of the general practitioner.

It may seem unnecessary for a teacher in a department which has already required the right to teach every undergraduate student to write such a letter as this, as Professor Gask's opinion cannot possibly affect their status. But I write because his views appear so reactionary that it is very difficult to discuss, with one who would appear to wish to go back over the past twenty years, the developments of medical education for the future. We have got to decide in the future, not whether there shall be any specialist teachers, but what subjects shall be allowed by their importance still to evolve and be split off from general medical and surgical teaching—I am, etc.,

T B LAYTON,

Recognized Teacher in Otology and Laryngology
University of London

Guy's Hospital S.E.1 Sept 1st.

THE TREATMENT OF FRACTURES

SIR,—Mr Gask, as a general surgeon (and a very eminent one), and Sir Robert Jones, as a specialist, have spoken (*BRITISH MEDICAL JOURNAL*, August 22nd, p. 317). As a general practitioner, may I crave space for a line? I was Sir Albinus Lane's house surgeon at Guy's, and I was under Sir Robert Jones (as consulting surgeon to the Western Command) when, during the first three years of the war, I was chief surgeon to the Lord Derby War Hospital, Warrington.

Two points strike me: the extreme necessity of every medical man being taught that the successful treatment of a fracture is as important as in abdominal success, the second is that the public should appreciate this point, and in all equity pay for it. It is very anxious work. The comparison between abdominal surgery and fractures seems ironical when my old teacher and master, Lane, is mentioned. War fractures and peace fractures in private practice are different propositions.

I base my fracture treatment on Scudder, Thomas's knee splint, and Jones's elbow sling. I am not certain how far plaster-of-Paris is useful, it has grave disadvantages. Simelun's methods for the femur (I visited his wards at Wimercux) are seldom needed in peace—I am, etc.,

Sevenoaks Aug 23rd

GERALD SICHEL

THE TREATMENT OF EMPYEMA

SIR,—After reading the discussion on the treatment of empyema in the *BRITISH MEDICAL JOURNAL* of August 22nd (p. 331) I noticed that one detail of the after-treatment appears to have escaped mention. All the speakers were agreed on the application of the general surgical principle of free drainage, and in achieving this object I have found posture a great help.

The position of the opening in the chest wall may vary according to the case, and it is usually, if not always, inexpedient to place it at the lowest point of the pus-containing cavity, but by varying the patient's posture one can bring the opening to the most dependent point. I usually open the chest wall, either with or without rib resection, well back, at or near the line of the angle of the scapula, as high up as practicable, and as soon as the breathing will allow it, often as early as the third or fourth day, raise the foot of the bed and remove all but one pillow for a considerable part of the twenty-four hours. I feel that by so doing the risk of failure to close the cavity is much diminished.

In scattered country practice with inefficient nursing, open drainage is the only course one can adopt, sealed drainage, with an attached tube draining into a bowl of lotion on the floor, as recommended by most of the speakers, requires two skilled nurses—I am, etc.,

Gillingham, Dorset, Sept. 5th.

W. W. GIFFIELD

TESTS FOR DRUNKENNESS

SIR,—I cannot help feeling strongly that the time has come when the ordinary tests for drunkenness should be examined, and if possible improved or added to. Dilated pupils, shaly hands, inability to walk a chalk line, and even the smell of alcohol, are not necessarily signs of drunkenness by themselves, or even if associated, as the questions of emotional stress and temperament have to be taken into consideration. If a committee of medical men with special experience in these matters, including possibly one or two magistrates, who have this class of case constantly before them, could survey the whole ground, and issue an authoritative report, stating the best tests, their order of value, and possible fallacies, I feel sure it would be of great value, especially to those medical men who may only occasionally be called upon to decide these questions, and naturally have not got the experience of divisional police surgeons in big centres. Since motor car driving has become so general the question has assumed great importance.

The drunk and incapable cases are a comparatively simple matter, it is the border-line cases that are the difficulty—I am, etc.,

HOWARD M. STRATFORD, F.R.C.S. Edin.,
L.R.C.P. Lond.

London N.6 Aug 19th

ULTRA-VIOLET LIGHT

SIR,—In defence of my statement that the ultra violet lamp costs £300 per 1,000 hours' run, the catalogue issued by Messrs. Watson (Bulletin No. 67), manufacturers of Dr. Hall's lamp, states:

Cost of cheapest tungsten rod, 4s. per inch
Cost of better quality tungsten rod, 6s. per inch
Rate of burning, 1½ inches per pair per hour

These figures apply to currents of 5 to 10 amperes at a voltage of 110.

A simple calculation will show in these figures the cost as above stated. The only way to use such a lamp at less cost is to lower the amperage input, and consequently the ultra-violet output, as this varies with the current consumed, but this would, of course, mean an increased time of exposure to get the same erythema. Alternatively one tungsten and one carbon might be used, but this also would imply an increased time of exposure. It would be interesting to know whether other users have kept records and how their experience compares. Could Dr. Daley have by any chance overestimated the number of hours the lamp was burning?

With regard to the life of the mercury vapour quartz lamp, the makers guarantee an effective life of 1,000 burning hours for ultra-violet treatment, stating that the original ultra-violet output is reduced by about 35 per cent. only in this time, the sole difference being that at the end of this period some of the lower wave-lengths are not transmitted. These figures are based entirely on the operation of the lamp at very high voltage, whereby the length of exposure may be reduced to a minimum. The mercury vapour lamp has an almost indefinite life when used for lighting, when visible radiations only are desired.

It is not necessary to provide a new lamp when the ultra-violet output is diminished. All that is required is for the quartz to be rebled at a cost of about £3—I am, etc.,

Birmingham Aug 20th

A. BRADSTON

SIR,—It may interest ultra-violet light workers to know that my expenses for running a K.B.B. 440 volt atmospheric quartz mercury vapour lamp for 542 hours have amounted to £5 1s. 7d., or about £9 10s. for 1,000 hours.

There is no question of replacing this lamp, as it can be cleaned at the cost of a few shillings when necessary—I am, etc.,

Smethwick, Aug 22nd.

CLYDE MCKENZIE, M.B.

TAR CANKER AND THE KANGRI

SIR—The kangri is a fire basket used during the cold weather by almost everyone in Kashmir, where the temperature often falls to 20° below zero—eggs are frozen so that they will stand up on a table without their shells—and the poor people have but one garment. The kangri is an earthenware bowl enclosed in a wicker-work basket with

a handkerchief over the top. To fill it hot wood embers taken from a fire are placed in the bowl and covered with a layer of ashes. Water is then sprinkled on the top to prevent the combustion becoming too active, and the bowl is held under the clothing by one hand withdrawn from the loose-sleeved garment. Children play in the streets barefoot in the snow with this basket held against the stomach and learn to arrange it skilfully at night under the one blanket which envelops the whole body and head. Accidents are frequent; fearful burns result from the upsetting of these basins, and fires are not unknown where houses are built of wood with thatched roofs.

Krangui cancer, which is an epithelioma, is fairly frequent but not common. The cases I have seen were in old women and involved the skin of the thigh, where the basket is often held in the sitting posture. The tumour and skin surrounding it and the fold of the gown were begrimed with black, looking like soot or fat, which resisted soap and water.

Krangui cancer is often quoted as an example of cancer produced by heat as an irritant, but it seems more reasonable to consider it as an example of cancer produced by trauma as the irritant. The wood used in the krangui is of many kinds, but one of the most popular for this purpose is the pine fuel washed down by the Sind river in its course from the glaciers through the hills covered with pine forests. At Ganderbal in summer men may be seen standing naked in the river up to the armpits with fishing nets much like those we use here for catching shrimps. With these they dredge the river for pine debris, which is sold as a popular fuel. It consists of small pieces rounded by the water, and when dried is a cheap and very hot fuel much liked for the krangui.—I am, etc.,

Horsesham

KATHLEEN VAUGHAN, M.B. Lond

SIR HARRY THOMPSON MEMORIAL FUND

SIR—A wish has been expressed by relatives of the late Major General Sir Harry Thompson, K.C.M.G., C.B., D.S.O., late R.A.M.C., that his services should be commemorated. They will contribute to that end. Knowing that, in addition, there are many of his friends (civil and military) who desire to join in some material tribute to his memory, I venture to ask you kindly aid in publishing this appeal for funds for this purpose.

The decision as to the most suitable form for the memorial to take should, it is considered, be left in the hands of the Harry Thompson Memorial Committee, who will be guided by the sum collected and the wishes expressed by the subscribers. Subscriptions should be sent to Messrs Glyn Mills and Co (Holt's Branch) 3 Whitehall Place, S.W. 1 who have very kindly accepted the trusteeship of the fund, and to the undersigned. All contributions will be acknowledged.—I am, etc.,

House Governor

Obituary

JAMES STEWART FOWLER, M.D., F.R.C.P. Ed.

Consulting Physician Royal Hospital for Sick Children Edinburgh
Secretary Royal College of Physicians of Edinburgh

The death occurred on August 24th, with startling suddenness of Dr J. S. Fowler, consulting physician to the Sick Children's Hospital, Edinburgh. Dr Fowler, who was 54 years of age, had appeared to be in his usual health, and a few hours before he died he was engaged in what formed his favourite summer recreation of boating with his daughter and some friends in the Firth of Forth, near Fife. After returning to his residence at Banchard, Elche, he became ill, lapsed into unconsciousness, and passed away in the evening.

James Stewart Fowler was born in 1871 and was the son of Dr J. S. Fowler of Glasgow, Demetrius. He was educated at Edinburgh Academy and later took his medical course at the University of Edinburgh, where he graduated M.B., C.M., with honours, in 1892. In the same year he took the English conjoint qualification of M.R.C.S., L.R.C.P. Lond. After graduation he acted as resident

physician in the Royal Infirmary of Edinburgh to the late Sir James Adcock, and as resident surgeon in the following summer to the late Dr P. H. MacLaren. At the same time he acted as President of the Royal Medical Society, to which he had been elected by his fellow students. Subsequently he spent a short time in post-graduate study at Vienna where he devoted himself particularly to the diseases of children. On returning to Edinburgh he became assistant physician to Leith Hospital and physician to the New Town Dispensary, Edinburgh. In 1895 he became a member of the Royal College of Physicians, Edinburgh, and in 1897 proceeded to the fellowship. In recent years he succeeded the late Dr Harry Murray as secretary to the Royal College of Physicians, a post he held at the time of his death. Becoming physician to the Royal Hospital for Sick Children, he completed his term of office in that capacity, and shortly before his death had been appointed consulting physician to this institution. He also held the post of physician to Chalmers's Hospital, Edinburgh, and was honorary pediatrician to the Royal Simpson Memorial Maternity Hospital. During the war he went out with a general hospital to Salomon, where he held the rank of temporary captain in the Royal Army Medical Corps.

For many years Dr Fowler had acted, along with Mr Alexander Miles, as joint editor of the *Edinburgh Medical Journal*, a publication which, under their able guidance, has attained its present high position of attractiveness and influence. Dr Fowler was a prolific writer on medical subjects, and among his publications were a clinical hand book on *Diseases of Children* published in 1899, and a smaller textbook on *Artificial Feeding of Infants*, published in 1909. Among his shorter publications were the article on mumps in the *Encyclopaedia Medica* (1901), on disease of the genito-urinary system contributed to *Curod Britten and Thomsen's Diseases of Children* on splenic anaemia of infancy, published in the *British Medical Journal*, 1902, on epidemic cerebrospinal meningitis in the *Review of Neurology and Psychiatry*, 1907 and on tuberculous sclerosis, which appeared in the *Quarterly Journal of Medicine* in 1910. Many other papers and articles from his pen appeared from time to time in the *Edinburgh Medical Journal*, dealing especially with diseases of children.

Dr Fowler was a man with a cultured, philosophic, and broad-minded outlook upon medical subjects which was greatly appreciated by colleagues who called him in consultation. His eminence as an authority upon recent diseases in children and his skill in treatment of this class of patient were universally recognized. He possessed a wide circle of friends in the medical profession and outside, by whom he was much beloved and who will greatly deplore his early death. He took an active part in the work of the Royal College of Physicians, and was identified with many other medico-social enterprises in Edinburgh, where his valued help and interest will be greatly missed.

He married, in 1902, Miss Edith Hudson, who was also a medical graduate, a daughter of Mr P. S. Hudson of Hyderabad. Mrs Fowler predeceased him in 1924, and he is survived by an only daughter.

ELIZA WALKER DUNBAR, M.D.,

Senior Surgeon Bristol Private Hospital for Women and Children

THE recent death in her 80th year of a medical woman who was practising so long ago as 1873 calls to mind the outstanding courage needed to break through the rigid conventions of that mid-Victorian era. Dr Eliza Walker Dunbar died suddenly on August 25th at her home in Oilfield Road, Clifton, where, despite her advanced age, she was still engaged in practice. Her long and varied experience, always at the disposal of the medical women of a younger generation, made her universally popular among them.

Eliza Louisa Walker (she assumed the name of Dunbar in 1874) was born at Balaram, Bombay, in 1845. She was a daughter of the late Alexander Walker M.D., of the Bombay Military Department, and sister of Dr A. Dunbar Walker. She had the advantage of completing her education begun at the Cheltenham Ladies' College, at Farnham-on-Moore. Thus, with a thorough knowledge of German, and already having an interest in things medical, it is easy to understand how she was attracted towards

the study and practice of medicine. This she relieved at the University of Zurich, where she studied from 1868 to 1872. She was granted the degree of M.D. of the university in 1872 on her thesis "Limbohe der Hun-Arten". After obtaining the doctorate she took a post-graduate clinical course in Vienna for a year, and on her return to Lugano in 1873 was appointed house-surgeon to the Bristol Royal Hospital for Sick Children. When, after the passing of Mr. Russell Gurney's Enabling Act in 1876, the King's and Queen's College of Physicians, Ireland, admitted women to its examinations, Dr. Dunbar, with four other women, obtained the qualification of the college. This entitled her to register her degree and diplomas in the Medical Register of the United Kingdom, which she did in 1877.

In 1874 Dr. Walker Dunbar, together with Miss Read and other supporters of the independence of women, had founded the Reid Dispensary for Women and Children at Hotwells, Bristol. In addition to being engaged in private practice she interested her friends in a project she had much at heart, and in 1895 succeeded in starting the Bristol Private Hospital for Women and Children in Berkeley Square, Clifton. She continued to serve on the surgical staff of that institution up to the time of her death. She was also for many years medical officer to the Red Lodge Reformatory for Girls, and to the Bristol Training College for Elementary Teachers, now the Department of Education (Women), Bristol University. In 1906 she published an article in the *Bristol Medical-Chirurgical Journal* on "The new theory and prophylactic treatment of puerperal eclampsia."

This wonderful and kindly old lady will be much missed by all who had the good fortune to know her or be under her care. To quote the words of a colleague, "Dr. Dunbar was essentially a pioneer, and to the end of her career she showed as outstanding qualities courage, perseverance, and pluck. She gathered round her, and retained throughout her life, a devoted band of friends and supporters, by whom the news of her sudden death was received with deep regret." Her remains were cremated at Golders Green on August 31st.

WILLIAM ODELL, M.D., F.R.C.S., Torquay

We regret to announce the death, on August 21st, of Dr. William Odell, at the age of 74, at his residence in Torquay. Dr. Odell received his medical education at St. Bartholomew's Hospital, he obtained the diplomas M.R.C.S. and L.S.A. in 1872, the F.R.C.S. in 1876, and graduated M.D. in 1901. After acting as registrar in the ophthalmic department at St. Bartholomew's Hospital and house-surgeon to the Hertford Hospital from 1873 to 1878, he carried on private practice first in Hertford and later in Toronto until 1889, when he took up residence in Torquay. Dr. Odell held the appointments of honorary consulting physician to the Western Hospital for Consumption, honorary consulting surgeon to the Louth House Institute, and honorary physician to the Temple Lodge Home. He was an honorary life member of the St. John Ambulance Association, and as local secretary of the Lpsom College Foundation he devoted a considerable amount of time and energy to its support. During the war he was physician to the Western Auxiliary Military Hospital in Torquay. He was an ex-president of the Torquay Medical Society and the Natural History Society.

Dr. Odell was elected a member of the British Medical Association as long ago as 1874. He was the Representative of the Torquay Division in the Representative Body from 1904 to 1909, where he was a great favourite, and held office as chairman of the Division 1906-07. When his death became known, a special meeting of the executive committee of the Division was held and a vote of condolence sent to his widow. Members of the Division attended the funeral and a wreath was sent. Dr. William Odell was a fine example of all that was best in "the old school of family practitioner"—kindly, courteous, dignified, the friend of all his patients, holding fast to good traditions and old ways of life.

Medical News.

THE annual dinner of past and present students of University College Hospital will be held at the Hotel Cecil, Strand, on Friday, October 16th, at 7.30 p.m., with Dr. Herbert Spencer in the chair. Tickets, price 12s. 6d. (not including wine), may be obtained from the honorary secretaries, Mr. Gwynne Williams, I.R.C.S., or Dr. T. R. Lillott, F.R.S., University College Hospital Medical School.

THE annual dinner of past and present students of St. Mary's Hospital Medical School will take place at the Connaught Rooms, Great Queen Street, W.C., on Monday, October 5th, at 7.30 p.m., with Mr. Leslie Paton, F.R.C.S., in the chair. The honorary secretary is Dr. Hope Go. se.

THE inaugural address at the Westminster Hospital Medical School will be given on Thursday, October 1st, at 3 p.m., in the board room of the hospital, by Professor L. A. Gardner, Litt.D., Vice-Chancellor of the University of London, who will subsequently unveil in the hospital laboratories a tablet commemorating Mr. A. J. H. Carlill's endowment of pathological research work.

THE Fellowship of Medicine announces that an intensive course in general medicine, surgery, and the special departments will be given at the Westminster Hospital from September 21st for two weeks. The fee is 3 guineas, or 2 guineas for either week. The Brompton Hospital will start a fortnight's course in diseases of the chest on September 21st. On Wednesday, September 23rd, and for the following three Wednesdays, Dr. Heald will give special demonstrations at the Royal Free Hospital, at 5.30 p.m. on treatment by electrotherapy. Full particulars and syllabuses of the courses, together with the Fellowship programme, may be obtained from the secretary, 1, Wimpole Street, W.1.

A two weeks' course in cardiology will be held daily from 10 a.m. to 4 p.m. at the National Hospital for Diseases of the Heart, Westmoreland Street, W.1, from October 5th to 16th, the fee being 7 guineas. The course will include lectures and clinical work, with pathological demonstrations and instruction in the use of the electrocardiograph, polygraph, and sphygmomanometer. Admission will be by special tickets which may be obtained from the dean at the hospital. Early application is advisable.

THE American Association of Obstetricians, Gynecologists, and Abdominal Surgeons will hold its thirty-eighth annual meeting at Hot Springs, Virginia, during the latter part of next week. On Wednesday, September 16th, there will be discussions on appendicitis, placenta praevia, mechanics of labour, and on preparation and treatment in labour. On September 17th, discussions on preventive treatment in obstetrical practice, on fibroid tumours, and on malignancy, will be followed by the annual address of the President, Dr. Asa B. Davis. The last day, September 18th, will be devoted to the reading of independent papers.

DURING the Leicester Home Life Exhibition which is to be held from September 16th to 26th a series of health talks has been arranged by the Leicestershire and Leicester Insurance Committees. The subjects to be dealt with include the production of clean milk, smoke abatement, dental hygiene, housing, education and health, prevention of tuberculosis, and infant welfare.

DR. H. A. J. NICHOLLS, C.M.G., was presented on July 31st with an address, a piece of plate, and a purse of sovereigns, on the occasion of his retirement from the appointment of Principal Medical Officer of Dominica. For the last forty-eight years Dr. Nicholls has been officially connected with the Leeward Isles and Dominica, and for four years acted as Governor of the latter.

ARRANGEMENTS are now being completed for the sixth congress of the Far Eastern Association of Tropical Medicine which is to be held in Tokyo from October 11th to 31st, more than 500 delegates are expected. There will be an exhibition illustrating the medical history of Japan, and a demonstration of home-made medical and surgical instruments, medicinal plants, and parasitological exhibits.

THE First London (City of London) Sanitary Company was formed in 1908, and on the outbreak of the war consisted of two officers and fifty-nine other ranks, when it was dispersed. In May, 1918, it had eighty officers and over 1,500 other ranks serving overseas. The history of the company has now been compiled, and contains an unusually interesting account of the actual work during the war. Various illustrations, and the inclusion of many references to the lighter side of sanitary section work, commend the book to a wider circulation than among the actual members of the section. The price of the book is 2s. 6d. (post free), and it may be obtained from the editor, Mr. George W. Foster, "The Laurels," North Kelsey, Lincoln.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W C 1**

ORIGINAL ARTICLES and ILLUSTRATIONS forwarded for publication are understood to be offered to the **British Medical Journal** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **British Medical Journal** must communicate with the Financial Secretary and Business Manager, **British Medical Association House, Tavistock Square W C 1** on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the JOURNAL should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the **British Medical Journal** are **MUSEUM 9561, 9562, 9563, and 9564** (internal exchange four lines).

The TELEGRAPHIC ADDRESSES are
EDITOR of the **British Medical Journal** at **Anthology Western London**

FINANCIAL SECRETARY AND BUSINESS MANAGER
(Advertisements etc.), **Articulate Western, London**

MEDICAL SECRETARY, **Mediscra Western London**

The address of the Irish Office of the **British Medical Association** is 16 South Frederick Street Dublin (telegrams **Bacillus Dublin** telephone 4737 Dublin), and of the Scottish Office 6, Drumshugh Gardens, Edinburgh (telegrams **Associate, Edinburgh**, telephone 4361 Central).

QUERIES AND ANSWERS.

CLUBS FOR DIABETIC PATIENTS

"E G" writes to inquire whether such a club exists in this country as the "Diabetic" in America. As the name implies it is a special club for diabetic patients, where they get meals suitable for their complaint prepared.

ACNE OF THE FACE

"A B" would be glad of suggestions for the treatment of acne of the face of seven years duration in a healthy girl aged 19. All the usual remedies have been tried including diet Turkish baths medicines vaccines and local treatment. After nine months there is very little improvement.

PHLEBIC DOUCHES

"G T B" asks—
(1) Can the P be injected? (2) How much in bicarbonate pint in the tube used? (3) Is my special rectal adds that his patient is elderly has sciatic and rheumatic pains, and is constipated and not relieved well by purgatives.

URETHRAL SPASM FOLLOWING THE PASSAGE OF METALLIC BOUGIE

"PREFLEXED" asks for advice in the treatment of the following case. A man aged 60 was operated on in 1916 for a stricture of the urethra by external urethrotomy. After the operation he passed a large metallic bougie once a month, but could never allow more than a month to go by otherwise the stream became too small and frequent micturition resulted. In 1922 he had a nervous breakdown. Since January 1924 passage of the usual monthly bougie is followed by a full stream but a few hours afterwards he has a desire to micturate can only pass a few drops with great pain and is relieved by passing a soft catheter and drawing off about 12 oz of urine. This suggests the occurrence of a reflex nervous spasm and had it occurred at the time of his nervous breakdown would have been so attributed, but it commenced two and a half years afterwards. The urine is normal with the exception of the presence of *B. coli* for which he has been treated by vaccines with little success. He has been advised to try a smaller bougie as the instrument may be too large but after using No 14 15 once a month the spasms continued. There is no great difficulty in passing the bougie showing that there is no real organic obstruction it is left in for an hour and withdrawn with some difficulty as it is very firmly grasped by the urethra and is followed by a little blood. Drugs have been tried—namely, morphine injections aspirin, phenacetin, potassium bromide tincture of hyoscamine with sodium bicarbonate and capsules of benzyl benzoate. The last alone gave any relief but not always. The following questions arise: Whether surgeons are passing too large bougies? Does the urethral canal vary in size in different individuals? How long should a bougie be kept in and how often should it be passed?

PREVENTION OF MIGRAINE

Dr G W CHEATER (Woodford Green) asks for information as to how attacks of migraine may be prevented. For many years the attacks have come in bouts of four or five in a month being followed by an interval of six to nine months of freedom before

the next series began. The remedies tried include phlebotomy, gelsium potassium bromide atropine luminal iron strichnine, and purgatives. Strict diet was without avail and both exercise and rest and also the abandonment of smoking had no results. Correction of the eyes was twice obtained in a twelve-month, but resulted in relief for about six months only. Dr Cheater is inclined to the theory that the migraine attacks are due to temporary swelling of the pituitary body resulting in pressure upon the optic chiasma. The attacks always start with homonymous hemianopia right or left headache occurs on the opposite side to the blindness. He does not believe that atmospheric or by way of the stomach or foreign protein poisoning is responsible. He asks whether examination of the optic disc during an attack in order to discover whether the veins are engorged so showing, the presence or absence of intracranial pressure, would be of use.

LETTERS, NOTES, ETC

TREATMENT OF EMPHYSEMA AT HARPOGATE

Dr R T MORRIS, C B I, M C P (Southfield, Harrogate) writes: Having had comments addressed to me on Dr Theodore Craig's letter in your issue of August 29 (p. 397) I beg to state I am not the Dr Morris referred to in that letter.

VACCINATION AND COMPLETE QUOTATION

Dr W G WILLOUGHBY (Medical Officer of Health, Lambourn) writes: In a small paper called the *Vaccination Inquirer*, the organ of the National Anti Vaccination League dated September 1st 1925 a statement has been made to the effect that at a meeting of the Natural History Society in Lambourn I stated: "I would rather sleep with a case of small pox than a case of influenza" and for having stated this I am alluded to as "a bonhomie sensible M O H". It will interest your readers to know that this statement is a part of a sentence which was complete to this effect: "because I have been vaccinated against small pox, and I keep myself re-vaccinated from time to time." The little paper is I understand, circulated to medical men and I must very well give the impression that I did not believe in vaccination. The facts are that I was giving an address on vaccination and similar matters at the meeting of the Natural History Society and was taking the opportunity of rubbing in the importance and advisability of vaccination and revaccination explaining carefully the reasons for my doing so. It is interesting to know that anti-vaccinators can take a part of such a statement as I made and twist it so that it would appear that my opinion is diametrically opposite to that which I stated in full at the meeting. The statement in the *Vaccination Inquirer* may not be a matter altogether of bad faith on the part of the writer in that paper for his information was got from a local paper in which a contributor who is a prominent anti-vaccinator, made the original misstatement.

SANITATION IN THE ALPS

Mr F F ROGET the author of *Alitude and Health* in the Chardwick Library series, writes to urge the importance of giving more attention to house hygiene when considering residence in the Alps for health or pleasure. Such an architecture of the house requires care in the drawing up of the lease or terms of the purchase of the laws of purchase and holding of real property and the incidence of rates and taxes, and the law relating to master and servant. Mr Roget points out that these matters were not discussed at the recent International Congress on Climatology at Davos of which an account appears on page 499 this week and that sanitary engineers, architects and innkeepers have special knowledge which will aid in obtaining the best results from sojourn in Alpine health resorts. The disposal of house sewage at high altitudes in the case of isolated dwellings is complicated by the alternate freezing and thawing of the snows, the fermentation of sewage exposed to the sun on a frost-bound soil and by the fact that the smaller streams may become almost solid ice. He adds that where sanitation is under the supervision of public or private responsible authorities the conditions are excellent but in isolated leasehold dwellings and even in some more numerous establishments, "many English clients do not know where they stand—literally." Therefore some caution is necessary some knowledge of the technique of sanitation and architecture and some scrutiny of the wording of a lease before chalets are acquired by hire or purchase. These chalets, being often the speculative work of local contractors or the venture of peasant owners of land are seldom built to serve the specific requirements of foreign purchasers. Mr Roget concludes: "There seems to be room here for a little piece of organization under medical patronage or for information given through the medical press so as to place in the hands of English people repairing to the Alps in search of health the means of protecting themselves against the risk of defective leases, imperfect sanitation, faulty architecture, and unsuitable sites."

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 36 37 38 39 42 and 43 of our advertisement columns and advertisements as to partnerships, assistantships, and locum tenencies at pages 40 and 41. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 108.

British Medical Association.

PROCEEDINGS OF SECTIONS AT THE ANNUAL MEETING, BATH, 1925

SECTION OF THERAPEUTICS
(INCLUDING BALNEOLOGY AND RADIO-THERAPY).

Professor R. B. WILD, M.D., F.R.C.P., President

DISCUSSION ON
THE THERAPEUTIC VALUE OF LIGHT

OPENING PAPERS

I—W. E. DIXON, M.D., F.R.S.,
Reader in Pharmacology and Assessor to the Regius Professor
of Physic, Cambridge

The physical basis of light is a series of waves in the ether which excite the retina to appreciation. The retina is sensitive to relatively few rays of definite wave length, this number forms a very small proportion of the total waves of a complete spectrum. The ultra-violet rays are of more rapid vibration and occupy a much greater portion of the spectrum than the visible rays, beyond them are rays emitted by vacuum tubes and gamma rays by radium, all these invisible rays can be detected by photography. The infra-red rays at the other end generate heat, and beyond them are the Hertzian rays used in radio telegraphy. The diagrammatic spectrum appended is an attempt to show the relative position and extent of these waves, the relatively small number which affect the retina, and the composition of the solar rays.

Local Action of Light

Any form of mild stimulation applied to the skin causes local effects on the skin and general effects on the body as a whole. The local action begins with an erythema, followed, if the stimulus is sufficiently severe, by oedema. These effects are produced by local dilatation of the blood vessels, and the cause of the dilatation is stimulation of the sensory nerve endings in the skin. The sensory nerves in the skin are connected by axon nerves with the vessels, and stimulation of sensory nerves causes reflex vaso-dilatation. Mustard applied to the skin produces no significant action on the part to which it is applied if the nerves have been previously severed and allowed to degenerate. The same is true if the mustard is applied to a portion of the skin in which the peripheral nerves have been previously paralysed by ethocaine or other efficient local anesthetic. Gooding and I have shown that the same mechanism of action accounts for the burns produced by dichloroethyl sulphide, the mustard gas of chemical warfare.

Prolonged exposure of the skin to the sun's rays also produces an erythema, this effect is not due to the heat waves, since staining the skin with penicillinate or coffee protects the exposed skin from the solar irradiation. The rays which produce this effect have not been clearly mapped, but those at the short end of the visible and the long end of the ultra-violet spectrum produce the maximum of inflammation, roughly speaking, the longer the wave-length the better the penetration and the more marked the action. This skin of 0.1 mm thickness allows only wave lengths greater than 3,600 Å to penetrate. By using ultra-violet rays from the mercury quartz lamp it is easy to give an exposure to the inner side of the arm which produces decided erythema. If the area of the skin is anesthetized by injections of ethocaine repeated from

time to time so that the area is kept anesthetized for two or three hours, then the application of the rays to the anesthetized area is found to have lost most of its stimulant properties and the skin is but little affected. The ethocaine itself has some stimulant properties and it is necessary to control the injections. Different people require considerable differences in length of exposure to produce comparable effects. The erythema produced by ultra-violet light on the skin appears then to be caused by the same mechanism by which mustard and other skin irritants act. How it happens that these rays stimulate sensory nerve endings and why people differ in susceptibility towards them we understand no better than we understand how mustard or mustard gas acts, except we have reason to think in the latter case that the effect is not due to any crude chemical change between the mustard and nerve endings, but that certain energy factors associated with the molecule and evidenced on apperception to the skin during its hydrolysis are at work, factors which are not exhibited in the chemist's structural formula.
